DR. GARLOCK remarked that iodide of potassium should be avoided in soft chancre; its effects were decidedly bad. He had found inunctions with mercurial salts very important in the treatment of syphilis, especially before the second stage, the symptoms of which it sometimes prevented from appearing.

DR. FLEISCHNER said the fact of the chancre being soft did not necessarily preclude syphilis. It was not uncommon to find a simple abrasion result in an ulcer and finally systemic syphilis become manifest, without there having been at any time local induration. The question of time of commencing syphilitic treatment might often be decided by the time which had elapsed between illicit intercourse and the appearance of the sore. A man who came to the doctor for treatment and acknowledged illicit intercourse would not be likely to mislead him with regard to date. If the sore appeared late, say twenty-one days after intercourse, he would not consider it necessary to wait for induration before commencing syphilitic treatment. Whether mercury were used by inunction or by injection, he thought made little difference. The latter mode probably gave quicker results, but that it was more effectual he could not see. As bearing on the duration of treatment it might be observed that some cases of syphilis terminated without treatment; they aborted. If, then, he subjected a patient to treatment and he responded very readily, why not, after a month's absence of symptoms, wait and keep watch? Was it necessary that an extra mild case be subjected to two years' treatment? He thought the treatment should be adapted to the individual case.

THE CHAIRMAN agreed in the statement that absolutely no hard and fast rules could be made for every case of syphilis. He also agreed in the remark that if a sore appeared at a given date, say a month, after a single illicit intercourse, syphilitic treatment might safely be begun, whether the sore was soft or hard: but in his experience patients usually had had intercourse at different times within a month or more, and they were likely to attribute a chancre to an intercourse of the previous week, whereas it dated from one of several weeks before. He called attention to a remark of Mr. Hutchinson which he had found of infinite value in diagnosis, namely: that the first chancre in the young man was almost always

syphilitic. He had called the attention of students to that fact many times. A man entering his clinic and stating that it was his first chancre, he could usually assure them, although it had all the appearances of a soft chancre, that within a month or two the patient would show distinct evidence of syphilis. Dr. Bulkley did not believe, however, in a chancroidal poison which could be isolated as the syphilitic poison could be. He believed the patient lost in strength when treatment was postponed, and he therefore began it as soon as he felt pretty sure of his diagnosis. As to how long to continue it, he could not agree with Dr. Fleischner. It would be safer, he thought, to keep all patients under treatment two years, and there were many who should be treated much longer. He would, however, allow them to marry after six or eight months' freedom from lesions. He has never known one who acted on that advice cause infection or transmit the disease to the offspring. He believed that during late lesions of syphilis there was no contagious element in the blood.

## COW'S MILK FOR INFANT FOOD.

*Read in the Section of Diseases of Children at the Fortieth Annual Meeting of the American Medical Association, June 1886.*

BY E. F. BRUSH, M.D.,

OF MOUNT VERNON, N. Y.

In India, several years ago, one of the Hindoo kings, "in order to atone for his cruelties, caused a colossal golden cow to be made, through the body of which he passed with profound reverence and made it the era from which all his edicts were dated." This historical fact is significant. We have practiced all manner of cruelties with the luckless infant deprived of its mother's breast; we have presented all manner of unfit substances to this small animal, whose only language is a cry, whose only desire is food. In fact, whenever a commercial enterprise finds itself burdened with some waste product that cannot be put to other use, it has been deemed a good substitute for mother's milk, and straightway the market is stocked with another "baby's food," and plenty of physicians to recommend it and plenty of babies ready for martyrdom. Now how can the physicians of the nineteenth century better atone for all their cruelties toward the human young than by causing a better cow to be reared, and from henceforth base all their edicts on the artificial feeding of infants on this better cow with a better milk product? I think that, with few exceptions, we are all agreed now that nothing excels good pure milk from good healthy cows for the artificial nourishment of infants, and if the great body of physicians put themselves about it with anything like the same energy they have

displayed in suggesting substitutes, they can so reform the breeding of dairy cattle and the handling of their milk that the suffering of the human young will be ameliorated to a far greater degree than was ever hoped for by the astute chemist who started out, years ago, to make not only a substitute for cow's milk, but also for that of the human mother.<sup>2</sup> It is this idea of a substitute that has led us away from the more important consideration of improving what nature has already presented to us. Just look at the improvement in the commercial line that the middlemen have made in their milk transactions. These men have reduced the purchasing of milk to a nicety hardly surpassed by the purchasers of gold and diamonds; they have worked down the price of milk from the producer to the lowest possible point; they have dropped fluid measurement and adopted weight as being more accurate; in butter factories they have invented an oil test that will indicate, in a very short space of time, the exact amount of butter a given quantity of milk will yield, and on this test the price of the milk is regulated; likewise the cheese factories have established a standard of solids in milk which also regulates the price. But all the improvements these men have made do not help us, notwithstanding the fact that our chemists, sanitarians and health authorities have followed in the wake of these men and endeavored to make us believe that the healthfulness of milk is dependent upon the total solids, fats, etc., that relate solely to its commercial value. A larger percentage of fat that is easily removed from milk does not improve it for our purpose; it matters very little to us whether a given quantity of milk contains 12 or 14 per cent. of solids.

In milk for infant feeding we should consider, first, the variety of fats, the manner in which they are emulsified and combined; second, the amount of albuminoids and their condition; third, the amount and variety of salts; fourth, the health of the animals from which it is derived and the food that has been consumed to produce the milk, and, fifth, the changes which the milk has gone through before it reaches the infant's stomach. When we come to understand all these conditions we shall readily perceive just what kind of milk we want, and exactly the kind of cow which, with a given variety of food, will produce the very best substitute for the infant in lieu of its own maternal breast.

Let us then first consider the fats. Taking the human milk, which should always be our standard, we find that these solids, according to the best authoritative analysis, occur in propor-

tions of 2.11 to 6.89.<sup>3</sup> Now this makes an average of 4.131 for human milk. From several hundred analyses of cow's milk in different parts of France, England and America the average of the chemist is 3.91. Thus you will see the difference, according to the chemist, between the two varieties of milk is very slight. I know, however, from the actual experience of practical dairymen, that cow's milk contains more fat than is indicated by the above figures. The lowest amount of butter obtained from mixed milks is 1 pound of butter from 25 pounds of milk. This would make the fat percentage 4. In drawing this deduction I am well aware that a pound of butter is not a pound of fat, but a pound of butter obtained from a given quantity of milk represents a pound of fat in that milk, because the quantity of fat in a pound of butter is exactly 84 per cent., and according to the latest experiments at agricultural stations only 84 per cent. of the fat can be obtained from the milk by the process of butter making. Now this percentage of 4 is a low practical estimate of the quantity of fat, for among dairymen, with special breeding and feeding, they get as high as 1 pound of butter from 14 pounds of milk, that is, 7.13 per cent. This is a higher percentage than has been found by any chemist in human milk. This is a practical fact, not chemical inference. It is very easy to understand where the fault in chemistry has been. The fat in milk is dependent upon the food the animal receives more than are the albuminoids, and we all know that very many of the varieties of fat contained in cows' feed are volatile, and the chemical methods of using heat dissipate these varieties of fat; hence the low percentage obtained by chemists. We must all admit that the fats contained in human milk, the product of an omnivorous, largely carnivorous animal, containing fixed and more stable fats, differ from those contained in the cow, an herbivorous animal, whose food holds more vegetable, volatile and unstable fats. Practically one is a yellow, unctuous, pleasantly odorous fat, as we see in butter; the other is colorless, waxy, decidedly different in odor, and, therefore, it can be easily understood that the chemist, who is obliged to use heat, will recover more fat from the human than the cow's milk. Thus we see that the fat is largely dependent on the nature of the food, and from the dairyman we learn that we can regulate the food of the cow so as materially to affect the proportion of fat secreted. We know very little about the chemistry of fats; so far as I have been able to ascertain, there has been but one analysis of cow butter fat made up to the year 1875. Wherever we turn, the analysis of Bromeis confronts us, and later English analysts, while finding this

<sup>2</sup> "Now I have come to the most important matter of the lecture, and that is the consideration of the proposition at one time sincerely made of substituting some other food for human milk as being a better food for infants." Abstract of a lecture before the New York Academy of Sciences by Prof. Albert R. Leeds, Ph. D., of the Stevens Institute of Technology. "Sanitarium," May 24, 1883, p. 325.

<sup>3</sup> "Composition and Methods of Analysis of Human Milk," by Prof. Albert R. Leeds. Transactions of the College of Physicians of Philadelphia, third series, Vol. viii, p. 23.

analysis to be all wrong, are unable to give us a correct one. These later analysts,<sup>1</sup> without ascertaining the proportions, have found in butter, palmitin, palmitic acid, stearin, stearic acid, olein, oleic acid, butyrim, butyric acid, caproic acid, caprylic acid, and capric acid. The fat of human milk has also been analyzed by Robin, several years ago, and also copiously quoted. I think that it is due to us from the chemists that we have some authoritative analysis of these milk fats, that we may know which, if any, of the fatty acids are the mischief-makers in milk, for I have no doubt that the glycerides and fatty acids from the decomposition of milk have more to do with the development of the poisons than the albuminoids have. The present popular method of analyzing milk by heat undoubtedly decomposes the fats, as is evidenced by the skin that forms on the surface of boiling or evaporating milk. This skin is undoubtedly the oxide of lipyl; it was at one time considered that it was coagulated albumen, but it does not form *in vacuo* and will continually form on the surface of boiling or evaporating milk as often as you remove it, and resembles very much the skin which forms on old paint pots that have contained vegetable oil. Furthermore, the condensation of milk for commercial purposes does not preserve the fats; hence, condensed milks are more or less skimmed, the better varieties having only the more volatile fats removed, otherwise they would become rancid. I am coming more and more to consider that the fats in milk are the bodies most likely to cause the digestive derangements of infancy, and when we know more of the composition and combinations of these bodies occurring in milk, many of the poisons, notably tyrotoxicon, will be less of a mystery than they are now.

Our second consideration will be directed to the albuminoids. Some time ago there arose a mild dispute between two chemists as to the amount of the albuminoids occurring in human milk, Prof. Meiggs asserting that there was only 1 per cent., while Prof. Leeds makes the variation from 0.85 to 4.86, an average of 1.195. Kœnig, an earlier analyst, makes the variation from 0.57 to 4.25. Some of these results give as high a percentage of albuminoids in woman's milk as we find in cow's milk, and I have no doubt in my own mind that the time and habit of extracting the milk has a deal to do with the amount of occurring albuminoids. In other words, when milk is extracted every two hours or less it can not contain as much of the cell material as milk from the same source extracted at intervals of twelve hours. This latter is riper, and it is the non-uniformity of the tissue which causes all the difference in the different occurring albuminoids. We know that during the incubation of eggs

casein is developed from egg albumen. This illustrates the ripening of albumen. Furthermore, take an egg just laid by the hen and boil it, and you will find immature albumen in it; that is, after boiling, instead of being thick and firm, like an older egg, much of it is milky. If boiled a few hours later all the albumen will coagulate perfectly, because it has had time to ripen. There is no doubt that the albuminoids in milk from healthy animals are all cell transformations, not an exudate, as are undoubtedly the fats and salts, because these latter we can influence by the food very plainly; but in health the albuminoids are constant without regard to the food, while during menstruation, pregnancy and other conditions, notably febrile disturbances, we find the fats and salts not materially affected, but the albuminoids are decreased, increased or totally changed, as we find in colostrum. The casein, besides being riper in cow's milk, by reason of its stronger growth, is intended by nature to coagulate into a hard mass, because it is the product of a cud-chewer for the nourishment of a cud-chewer, and the reason why it does not always coagulate in the infant's stomach, as it does in that of the calf, is that the latter animal's stomach secretes a principle called chymosin; this is the principle that curdles cow's milk, and it operates either in an acid or an alkaline medium. Pepsin will not coagulate milk, and hence the hard coagulum of cow's milk that sometimes forms in the infant's stomach is due to acidity of that organ, and this acidity is not always the fault of the stomach, but of the milk itself. The variations in the chemistry of the albuminoids found in cow's milk would not be surprising to any one if he could examine into the condition of some of its mammary sources, for often it will be found, on dissecting a cow's udder, which I always do when making an autopsy on a cow, that there are old cicatrices, one or more quarters of the udder intensely inflamed, sometimes a mamiferous duct clogged with a calculus or a clot of fibrin, and besides these pathological conditions the mammary gland is subject to benign and malignant infiltrations, bacillary tubercular deposits, and eruptive diseases of the skin involving the gland and ducts; therefore, that fibrin, serum and albumen in various forms are found in the cow's milk is not surprising, and it can safely be assumed that any variation in the albuminoids from the normal casein can be ascribed to sickness on the part of the animal producing the milk.

We next come to the salts contained in milk, and it is remarkable how few analyses have been made to determine the salts or minerals that are contained in this fluid. Heidlin's analysis, copied everywhere, seems to be the only exhaustive one of the salines in cow's milk made during the present century. It seems to me in this case too that

<sup>1</sup> Hahner and Angell, "Butter: its Analysis and Adulterations," London, 1877.

it is time for the chemist to teach us something more. There probably never was a time, in our era at least, when milk was attracting so much attention as now, and still all our chemists are content with the total solids, fats, albuminoids and sugar—just what the butter and cheese makers want to know. From this much-quoted analysis of cow's milk salts we learn that milk contains, in varying proportions, the phosphates of lime, magnesia and iron, the chlorides of potassium, sodium and iron, and free soda. Robin gets from human milk, in addition to the foregoing, carbonate of lime and soda, phosphate of soda and the sulphate of soda, and potash. We have no means of knowing how constant is the occurrence of any of these salts in milk, or under what conditions they are modified; we do know, however, from the experiments of Fehling, that many of the drugs administered to the milking female are excreted in the milk. Therefore, we can safely assume that the saline constituents occurring in milk are influenced both by the health and food of the animal. That the phosphates are craved for by the milking cow is evidenced by her habit of chewing old bones and the like, and that there is a lack of this element of food is not to be wondered at, when we see herds of milking cows pastured on old, worn-out lands. The practical farmer knows that exhausted pasture lands need, more than anything else for their rejuvenescence, the phosphates, and we know that in our nutrition we need them also. The land on which a cow is pastured will indicate pretty fairly what we may expect to find in her milk as salts. We have all noticed the excessive growth of sorrel on exhausted land, and can it then be a subject of wonder that some kind of a vegetable acid should be found in the milk of animals that are obliged to include this variety of food in their summer rations, and sour ensilage or spoiled brewery grains in their winter feed? Theodore Hänkel's discovery of citric acid in cow's milk, to the amount of 0.9 and 1.1 grams per litre, is just what might be expected.

Sugar, I think, in milk has always been over-estimated as to its nutritive value, because we know that carnivorous animals do not secrete sugar to any appreciable extent, at least so the chemists tell us; and when we see a small slut nursing seven or eight puppies and keeping them all fat and in a thriving condition, we can easily imagine that sugar is not one of the necessary elements of food; while, on the other hand, we know that the gross result of condensed milk feeding, where the sugar is in excess, is not good. In regard to using the commercial sugar of milk as an addition to cow's milk for infant feeding, I think it is a mistake, as there are undoubtedly all the other crystallizable salts with the milk sugar, and, consequently, we can know very imperfectly what we are feeding an infant with

when we are giving it milk sugar. If the milk from which the sugar was crystalized contained improper vegetable salts, these would undoubtedly become crystalized with the sugar, and many of the proper salts would have become changed to the lactates. Therefore, I think, if sugar is to be used at all, although I deem it of doubtful necessity, the pure cane sugar is undoubtedly the best, because you know just what it is. When we consider the chemistry of milk as we find it in the books, what does it all amount to? The chemist has given us to understand that the needs for bodily nourishment are a certain amount of the albuminoids, carbo-hydrates, fats and salts. We can, therefore, from some of the cheap cereals, make this ideal food, and for one cent have as much in nutritive value as we get in milk at a cost twenty or thirty times greater. Then why do we give milk? Because we have tried the chemist's ideal food with the infants at least, and however admirable the theory may be, in practice it is a failure. Nature does not make so close an allowance that there is nothing to spare and no margin. She does not measure food by the rule of three, always exactly in the same proportions. Let us examine the work of the chemists themselves, and we find in human milk a standard that we cannot ignore, the albuminoids varying from 0.85 to 4.86. Therefore, let us not deceive ourselves with the popular error of the day, namely, that milk must contain just such a proportion of solids, and solids not fat, and so forth, to a chemical nicety; but let us look into the cow-house and see what goes through the cow to produce the food for infants, and what kind of an animal she herself is. Prof. L. B. Arnold, as good an authority as we have in this country on dairy matters, says, "Milk is the scavenger of the cow's body." What would be the sense of taking a sample of water from a sewer and asking a chemist to examine it for sewage; and so, when we go into a dairy stable and see dirt and filth, disease and improper food, need we ask the chemist to ascertain the total solids, fats, etc., to find if the milk is fit for infant food? When this fluid will not properly nourish an infant, it is not the cow's milk *per se* that is at fault, but it is either a pathological condition of the cow, or improper food or care, or the conditions through which the milk has passed on its way from the cow to the infant. It is safe to say that if we had devoted the same attention to the cow, and if the same amount of money that has been spent on the various substitutes had been devoted to the improving of her condition, the infant, at least, would be better off.

Now we can assert that cow's milk is the best food for the artificial feeding of infants, and when this fails the fault lies in one or the other of the following conditions, or several of them combined: First, a faulty condition of the cow her-

self, and this will be indicated by the condition of the albuminoids; second, improper food or an improper manner of feeding and caring for the animal, and this will be indicated by the fats and salts; third, improper handling of the milk after it is taken from the cow, and this will be indicated by the ptomaines and extractives. A proper understanding of these three sources of danger will make the feeding of infants a simpler matter than that offered by any of the substitutes, and be, at the same time, a more rational method. We shall consider the conditions of the animal that render her milk unfit for food. The cow is a unique beast, differing in many respects from any of our other domestic animals. One of her peculiarities, that has caused a deal of confusion among veterinary writers, is her normal temperature. Several years ago I searched diligently in books devoted to bovine pathology to find the normal bodily heat of the cow, and the confusion was puzzling. It is variously stated at from  $98^{\circ}$  to  $101^{\circ}$  F. I myself made several hundred thermometrical examinations under varying conditions, and found that the temperature is not constant in apparent health, as it is, within very narrow limits, in the human subject. Of course we cannot tell to a certainty how near to health a dumb creature is. The standard we have to adopt with these animals is that they are in health when they perform their functions with profit to their owners. Certainly there are many slight ailments that do not carry the animal beyond this limit. Therefore, the varying temperature in the cow may be due to slight ailments that do not demand the attention of the veterinarian. The average temperature of the cow in apparent health I have found to be  $102\frac{1}{2}^{\circ}$  F., ranging from  $101\frac{1}{2}^{\circ}$  to  $103^{\circ}$ . This, you will perceive, is a peculiarity of the cow, and none of the other large domesticated animals maintain so high a bodily temperature. Another peculiarity of the cow is the constant employment of her generative functions. She is always milking or pregnant, and both the uterus and the mammary glands are employed almost constantly at the same time; hence her nervous functions are exaggerated. Therefore, with an abnormally high temperature—for I have found that bulls and steers have not so high a temperature as the milking cow—and with an unnatural functional activity of the organs of generation, she is used also as a machine to transform food into milk, and it is astonishing to what capacity she has been trained in this direction. With four stomachs, the first alone with a capacity of 60 gallons, she simply eats, and she will eat anything. In health she is always either eating or chewing her cud, and her pedigree sometimes shows the closest consanguinity in her breeding. Now, when we consider all these unusual conditions, is it at all to be wondered at that the ordinary dairy cow is,

as a rule, an unhealthy animal, more prone to bacillary phthisis and scrofulous affections than other animals? Her nervous system is more subject to severe shocks, and, in fact, she is a delicate creature. Her attendants are not usually either mild or cleanly, nor is her housing always the best.

Our next consideration is the feeding and care of this nervous and delicate animal. The ordinary dairyman receives for his milk  $1\frac{1}{2}$  to  $2\frac{1}{2}$  cents per quart. At this low price received by the producer he cannot usually give his cattle just the best food. I noticed in a dairy journal this summer an estimate from the New York Dairy Commissioner. Taking the milk received at the creameries as a basis, the average income from each cow is about \$25 a year to the producer. This is almost 7 cents a day, from which the dairyman has to buy food and pay for labor. This sum alone would not begin to pay for proper food for the animal; hence the farmer is driven to every known expedient to keep his cows in milk, and the profit being so small, if there is any profit at all, he must utilize every drop of milk, whether the animal giving it be sick or well. In this state of affairs, is it not natural that all the cheap foods, such as brewery grains, distillery slops, the refuse from starch factories, enter so largely into the food from which our daily supply of milk is produced. Of course this condition of low price and improper feeding does not apply to every dairy, but after years of experience I have no hesitation in saying that it applies to the great majority of dairy farms surrounding New York City, at least. I have personally inspected small dairies where the sole article of diet was swill gathered in the city. Good food is to the cows, of course, the prime absolute essential for the production of good milk, and unless the public are willing to pay more for their milk than they do at present, a reform in this direction cannot be expected.

The handling of milk after it leaves the cow is the next important consideration. Owing to the cow's natural high temperature,  $102^{\circ}$  to  $103^{\circ}$  F., the milk, when drawn, must cool rapidly, and this first cooling taking place in the cow-house, the milk is, of course, more or less affected by the conditions generating odors. If these odors are not very bad they can be removed, more or less perfectly, from the milk by a process of aeration. This can be accomplished either by pouring the milk from one vessel to another in a thin stream in the presence of a pure atmosphere, or on a larger scale by pumping pure air into it by a suitable machine. One of the most dangerous methods that I know of for killing the odors that milk absorbs from dirty stables or improper food, is that recommended by many practical and otherwise sensible men, namely, the addition of nitrate of potash, that is, common saltpetre. It is very

easy, from this addition of nitre, combined with the glycerides and sulphates already contained in milk that is decomposing, to figure out chemically bodies approximating to nitroglycerine. It is suggestively strange that the toxic effects of nitroglycerine are similar to those of tyrotoxin. The often reported detonation of this latter extractive, while undergoing examination in the laboratory, is also suggestive of the properties of nitroglycerine. The addition of chloride of lime, which is also recommended for the same purpose, although apparently a less dangerous chemical compound, should, nevertheless, be prohibited. Soda is also added to milk sometimes to delay the souring process. The prohibition of this chemical may be viewed in the light of a stultification, when we consider the large amount of bicarbonate of soda that is used at the present day in one of the popular methods of feeding infants. I think it is no less reprehensible on the part of the physician than it is on the part of the dairyman. No chemical substance whatever should be added to cow's milk by the dairyman. Milk that is procurable too far away to reach the child within a few hours should not be used for infant feeding. The different degrees of temperature through which it must pass in its transit by country wagon, railroad train and city express are productive of changes that cannot but deteriorate the quality of the milk. It is well known that light, as well as heat, is one of the elements that hasten decomposition in milk; hence, the now popular method of serving milk in clear glass bottles is also a popular error.

No milk should be served by the milkman for infant feeding after it is twelve hours old, nor should it be served to the infant while it is warm, immediately after leaving the cow, for I have found by actual experiment that cow's milk, while still retaining the animal heat, if taken into the stomach, would coagulate into a solid mass; but this coagulum is not so hard and rubbery as the curd we see sometimes formed when milk is too old. In regard to sterilized milk, I am of the opinion that it is far better for us to make an effort to improve the quality of milk to such an extent that it will be needless to sterilize it, because, of course, sterilized milk must take its place with condensed milk and other varieties of preserved food. If we cannot improve our milk, then, of course, sterilization ought always to be practiced. Notwithstanding that it is a preserved food, like condensed milk, it is not necessarily skimmed or sweetened, as the latter is.

Having thus outlined the condition of the milk we get and the reasons why it is not always good, let me in the next place suggest remedies for the existing evils. First, in regard to the cow herself. No cow that is bred for a butter-maker should ever be used to furnish milk for infant feeding. The ideal butter-cow is too closely in-

bred and, consequently, too nervous; there is too much free fat in her milk. The ideal cow to furnish milk for our purpose should not be too finely bred and with little, if any, consanguinity in her breeding. She should not have had her first calf till she was in her third year; her milk should not be used after she is six years old, unless she has been spayed; she should be of a quiet disposition, her surroundings clean and quiet; she should be stall-fed always while giving milk for infants; her food should be hay without weeds, ground oats bran, flaxseed meal, roots (beets and carrots) bone-meal and salt—in the winter, corn-meal in addition, and in summer, in lieu of dry hay, green cut clover or grasses free from weeds. She should be curried daily and well bedded, and in winter the water she drinks should be slightly warmed. The milk should be aerated and cooled as quickly as possible. It should then be put into opaque bottles and securely closed.

Now, why do we not have this kind of cow and obtain this quality of milk from our milkman? The very first and prime reason is that milk is sold altogether too cheap. The producer, as I have before mentioned, gets about 2 cents a quart; the railroad or the carrier gets 1 cent a quart for all handled, and the distributor gets 5 cents a quart for peddling to the customers; therefore, the consumer pays 8 cents. This variety of milk does not usually agree with the child, and, therefore, the consumer is advised to buy some of the baby foods as an addition to the milk, and this increases the price of the food to something like 15 to 20 cents a quart. Now, if the producer got this extra amount of money he could buy better food and better cows, exclude the milk of sick animals, and altogether improve the quality of his produce. But would he do it? That is the question. Still, it would be more humane to make him do it when he is making a living, than under circumstances as they exist now. So the question of a purer supply rests very largely with the medical adviser. Instead of recommending commercial baby foods in addition to doubtful milk he should advise the parents to purchase milk at 12 or 15 cents a quart, and when the infant gets sick from digestive troubles then lay the blame where it is justly due, to the milkman, and he will lose his customer. The supply of baby milk in cities should be kept entirely distinct, and should be procured from those farms that are situated near enough to the consumer to get the morning's milk of the day of delivery. The dairies supplying this variety of milk should be under strict sanitary surveillance, for no matter how good a condition a cow may be in, if she is in heat, has sustained an injury, or is sick in any manner whatever, her milk should not be used for infant feeding until she has completely recovered. The ideal dairy for supplying infant food should be composed entirely of spayed cows,

and thus one constant source of nervous functional disturbance would be eliminated. In my own herd I have several spayed cows whose milk I supply for infant feeding. These animals are much more quiet in disposition, they give a more constant and uniform supply of milk, and seem to enjoy a more even degree of health than the cow who is occasionally bulling and becoming pregnant when giving milk.

DR. JOHN A. JEFFRIES said that he was much interested in Dr. Brush's paper, as he held the study of cow's milk to be very important. So long as our present customs remain, many children must be artificially fed, and cow's milk properly prepared is the best available substitute for the breast milk. By means of some mixture, such as Meig's, the milk can be made to more closely resemble human milk. It still remains that the albuminoids differ, and the same is probably true of the fats. The nature of the fats requires more attention, since some recent physiological work shows that the nature of the fat fed to animals affects the fat deposited in the system. He could not agree with the reader that cane sugar was better than milk sugar. The latter was now carefully prepared, was the natural food and was less easily fermented in the stomach and intestines.

As to sterilization, he thought it was very important. When milk only a few hours old was used he never had it sterilized, but if the milk must stand for some time before use it should be sterilized shortly after milking, before altered, in the country. The large number of children now fed on sterilized milk with the most happy results proved the value of the method beyond question. The three points in the artificial foods were a healthy cow, properly preserved milk, so modified as to resemble human milk.

DR. EARLY, of Ridgeway, said that while in the Pennsylvania Legislature during the pending of the pleuro-pneumonia bill he made an investigation of the dairies in the neighborhood of Philadelphia. He found many diseased cows among them, and in a stable at Camden, where six out of thirteen cows died, he found the owner selling the milk.

DR. CHRISTOPHER, of Ohio, was very much pleased with Dr. Brush's paper. He had recently made an investigation of the dairies of Cincinnati. In one dairy of great excellence he noted that the cows were thin. In distillery dairies the cows were fat. Thin cows taken there quickly fatten. Moreover, the urine of the swill-fed cattle was passed with great frequency and in large quantity, while that of properly fed cows was small in quantity and passed infrequently. Distillery cows give milk rich in cream and accumulate fat. This was without doubt a pathological condition resulting from deficient oxidation. This milk

further undergoes decomposition with great readiness and is acid in reaction.

DR. GATES considered Dr. Brush's paper one of great value. In his experience lean cows are the best milkers.

DR. BRUSH considered Bordin's condensed milk as good as it is possible to make it, but no condensed milk can be made to contain all the constituents of fresh milk. It is preserved food and, as such, is open to the same objections as all preserved foods. Experience has shown that they do not properly nourish the tissues. What the difference is cannot yet be demonstrated, but there is something necessary for proper nutrition. Distillery-fed cows are not fat; the appearance of fat which they show is due to an oedematous condition. He has often made post-mortem examinations of such cows, and finds the tissues blubbery instead of composed of firm adipose tissue.

## THE CLINIC.

### A STUDY OF THE LOCATIONS OF 7881 PRIMARY CARCINOMATA AS ILLUSTRATING THE PROBABILITY OF A CANCEROUS MICROBE.

BY EDMUND ANDREWS, M.D., LL.D.,

PROFESSOR OF CLINICAL SURGERY IN CHICAGO MEDICAL COLLEGE  
AND IN MERCY HOSPITAL, CHICAGO.

[Reported for THE JOURNAL.]

*Gentlemen:*—It is not yet histologically proved that there is a cancer microbe. Prof. H. A. Johnson of this city, observed objects some years ago which he thought might be of this nature, and more recently Thomas, of Dorpat, and Scheurlein, of Berlin, have each discovered organisms which made a similar impression on their minds, but the final proof of their surmises is not yet forthcoming. To-day I wish to call your attention to some important clinical facts bearing on this subject which render a cancerous microbe a probability and, therefore, a proper object for search. True, these facts do not positively prove the conclusion, but they point so strongly toward it that they may be said almost to settle the question.

You are aware that many pathogenic bacilli and micrococci have their original existence outside of the human body; that their spores float in the atmosphere like inanimate dust, in a dormant condition, but when they light upon exposed tissues wet with animal secretions they spring to activity, show a swimming power, and traverse considerable distances, multiplying as they go and generating disease. If the cancer germ exists at all, its actions prove that it has these qualities.

You are also aware that all primary carcino-

mata begin in the deeper epithelial cells, close to the basement membrane. We sometimes speak of epithelial cancer, meaning a slightly modified form of the disease; but in a certain sense all primary carcinomata are epithelial; that is to say, they all originate in epithelium. A few eminent authors claim to have found true primary carcinoma in tissues deeper than the epithelial surfaces, but the cases are excessively rare, and I very much doubt the accuracy of the observations. Now, bearing these things in mind, allow me to lay before you certain clinical laws, and to follow them with statistics.

1. Other things being equal, primary carcinoma is most frequent on those surfaces which by their position would be most accessible to free swimming microbes or spores derived from without the body.

2. The liability to cancer is increased if the epithelial surface is so situated that the spores can remain upon it for at least some hours without being swept away, as on the lower lip; but the liability is greatly diminished if the parts are frequently swept off, as the globe of the eye by winking, or the œsophagus by swallowing food and drink.

3. The liability to cancer is great if the membrane has vast numbers of deep glandular follicles into which the spores can penetrate and lie free from disturbance and have direct access to the more delicate epithelial cells, as at the pyloric end of the stomach and the follicles of the mammary glands.

4. Those portions of the skin which are usually uncovered are oftener attacked than those covered with clothing and constantly brushed by its friction. The skin of the face, for instance, produces more cancer than all the covered portions of the integument combined.

5. As might be expected, there are a few seeming exceptions to these rules, but so few that they do not break their general force.

To make good these clinical laws I have, with considerable labor, made a collection of 7881 cases of primary carcinoma, gathering them from my own records and from extensive reports prepared on both continents, and I have tabulated them for your instruction. The first table shows the sources of my information and the number of cancers in each part of the body.

I omit all cancers of the lungs, liver and lymphatics, because these are almost all secondary. It is the primary cancer alone which is derived from without. The secondary ones are all mere infections from the primary.

First let us consider primary cancers of the alimentary canal, as given in the table.

The prolabium of the lower lip, though so small a surface, gives us the surprising number of about 481 carcinomata. In proportion to the surface exposed it develops more cancers than

any other part of the body. The reason is not obscure. The lower lip is in such a position that vast numbers of germs from the air, from food and from drink may light upon it and lie there hours together without being dislodged. Finally the cracks and abrasions on it are very frequent from exposure to sun, wind and accidents, and from the pressure of the pestiferous stems of clay pipes, and these cracks, etc., furnish spots of access where the spores can reach the deeper epithelial cells. It is natural, therefore, to expect the disease at such a spot.

LOCATIONS.	Total No. of Cases.	From records in Mercy Hospital and in private prac.	From other American rep.	From Hosp's of London.	From Hosp's of Paris, 3 yrs.	From Imper' Hosp. in Vienna, 7 years.

Grand total . . . . .	7,881					

Now passing inward we find the tongue, though presenting a larger surface, has less than half as many cancers as the lower lip; still it gives us 196 cases. Vast numbers of spores, after passing by the lips, may light on the tongue and lodge in the forest of papillæ or on ulcers made by ragged broken teeth. If they could remain there undisturbed they might find as safe a nidus as on the lip, but the constant friction of the organ in the mouth and the frequent baths of saliva may wipe and wash away most of the germs, so that attacks are less numerous upon it than upon the lower lip.

The salivary glands give us only 30 cases of cancer. The orifices of their ducts in the mouth are very small and few spores would find them. Then these ducts are swept out many times a day by swift currents of saliva, so that only rarely could a swimming microbe be expected to make its way successfully to the gland.

The other parts of the mouth present us with 244 cases, mostly beginning at the edges of the gums, where germs might lodge in the crevices between the gums and the teeth.

The whole mouth thus gives us 951 cases of cancer, a large number, but just what we would expect from an organ so situated as to be constantly receiving external microbes every minute of both day and night.

The œsophagus gives us only 59 cases. This is precisely what we should expect of an organ which is swept clean throughout its entire length by every mouthful of food or swallow of water. Of the few attacks that do occur the major portion are at the lower part, where the sphincter of the cardiac orifice often detains small portions of food for some time, and where the follicles of the mucous glands are deeper and far more numerous than in the upper portion, so that a lodgment of swimming germs is more likely to occur.

Figure 1.—Peptic gastric gland. (Gray.)

The stomach gives origin to 1945 cases, a startling array, equal to one-quarter of all the primary cancers of the entire body. I suppose this is mainly due to two causes. In the first place, whatever is swallowed remains there for hours; and, secondly, the mucous membrane of the stomach is honeycombed with many thousands of deep follicles, into which the germs have plenty of time to enter and obtain a permanent lodgment where they will be secure from being swept away. For a similar reason there is a difference in the

susceptibility of the two ends of the organ. Most of the stomach cancers originate near the pyloric extremity, and correspondingly the follicles are deeper, more numerous and more complicated at that end. The stomach, therefore, is remarkably well adapted to give lodgment to microbes, and perhaps few men would escape the disease but for the fact that its secretions in a state of health are powerfully germicide, destroying not only the yeast plant and most other ordinary ferments, but also many pathogenic bacilli, including probably the cancer spores. It seems probable that carcinoma can attack the stomach only at such times as the secretions are below par in germicide power, just as in such circumstances the food may undergo acid fermentation, making a sour stomach, or even putrefy from the action of putrefactive bacilli.

Figure 2.—Glands at pyloric extremity of stomach. (Gray.)

It follows that probably very few cancer spores reach the intestines in a living condition, and we should expect primary carcinomata to be few in these viscera. Accordingly our table gives us only 127 cases. This small number is the more striking because the walls of the intestines present nearly ten times the area that the stomach does, and they are specially subject to irritations and inflammations of many kinds. However, as we approach the rectum and anus, where germs can enter from without, primary carcinoma becomes more abundant. The anus and lower half of the rectum, though constituting only a very small

fraction of the intestinal surface, give us 280 cases, or more than twice as many as all the rest of the intestines put together. This is one of the many facts which constantly tend to make the clinical surgeon feel that the carcinomatous infection comes from without the body. Another fact pointing the same way is this: Cancer of the upper half of the alimentary canal occurs far downward along its course, because the germs are carried along with the food and drink; but at the lower outlet primary cancer rarely originates more than three inches above the anus, because the downward motion of fæces prevents cancerous spores from ascending except in a few cases; hence the very striking fact that probably nine-tenths of all the primary carcinomata of this location are within three inches of the verge of the anus.

Figure 3.—Peptic glands of stomach after treatment with alkalis. (Frey.)

If we consider the male genito-urinary tract we find a similar condition. The penis furnishes us 62 cases, nearly all on the glans and prepuce, where germs can lodge and remain undisturbed, while the urethra, which is swept out by a swift current several times a day, only presents 4 cases. The prostate and the testes are, so to speak, terminal stations, and though many spores must fail to arrive there, yet those that do are safely lodged and can germinate undisturbed; hence we have more or less cancer of the testes, prostate, bladder and even kidneys reported. The figures for the testes are utterly worthless in most hospital reports because of an error in diagnosis by which a great part of the tubercles of the testes have formerly been reported as cancer; and as I have been unable to collect a sufficient number of cases which were proved by microscopic examination, I might have done well to omit that organ from

the list, but after reflection I decided to retain it. Perhaps, also, I ought to have rejected the kidneys, for in most hospital reports a large number of cases both of tubercle and of sarcoma of these organs have been erroneously tabulated as cancer by careless pathologists.

In the female genitals the cancers of the vulva and vagina are few. These organs are not terminal stations and not specially subject to irritation; but the cervix uteri, presenting abraded spots in millions of otherwise healthy women, is a natural prey to any such swimming germs as we have supposed to be the cause of cancer. Hence carcinoma of the uterus is exceedingly abundant, giving us 2,308 cases, which is almost one-third of all the primary carcinomata of the body. It is noticeable also that almost all cancers of the uterus begin not high up, but at the cervix. Fig. 4 is a portion of the uterine canal twice the natural size, showing how completely it is honeycombed with follicles adapted to furnish lodgment to swimming spores. Fig. 5 shows the follicles more highly magnified, and displays impressively their adaptation to retain pathogenic microbes in their recesses.

Figure 4.—Uterine follicles enlarged two diameters. d d d, follicles; a a a, orifices. (Am. Syst. Gynecol.)

The mammary gland presents remarkable statistics. The number of cancers of the organ in our table is 1,232, the greatest number of any organ except the stomach and the cervix uteri. At first glance this seems contrary to the rule, for external spores can only enter through the nipple, and that is a small organ, covered and brushed with the clothing and often supposed to be dry, except during lactation. However, lac-

tation covers a good deal of a woman's life during child-bearing age. Furthermore, the orifices of the milk ducts, even when not lactating, are frequently moistened with a very slight exudation of mucus, and at other times with perspiration. For these reasons there is abundant opportunity for swimming spores to light on the parts and enter the interior. In active lactation they would be mostly swept out again by the rush of milk, but in the non-lactating periods they would make their way undisturbed to the follicles and find themselves eminently in a terminal station, from which nothing could dislodge them. The almost total absence of carcinoma from the male breast falls in well with this theory, as the smallness of the nipples and the tightness and dryness of the orifices of the milk ducts are almost an absolute protection from the admission of germs of any kind.

Figure 5.—Intra-uterine glands. e, epithelium; g g., glands; c t., connective tissue; v v., blood vessels; m m., sub-mucous layer. (Am. Syst. Gynecol.)

There is a striking difference in the liability to primary cancer between those portions of the skin which are habitually uncovered, as the face and hands, and those which are covered with clothing and habitually brushed off by its friction. The face and hands alone give us 366 cases, while the whole of the covered portions of the skin together furnish only 191 cases, as if the clothing served in some way to prevent the lodgment and development of germs by its protective and by its brushing action.

This liability of different surfaces to cancer in proportion to their exposure to germs, and their ability to afford them an undisturbed lodgment, is still more strikingly shown if we compare equal areas of the different surfaces. I have calculated the areas of the different organs and the proportion

of cancer to the same area in all. Suppose the intestines to present one cancer on a given area of surface, then the number of cancers on the same area of other organs will be as follows:

*Table showing the liability of equal areas of different surfaces to cancerous infection, the liability of intestine being assumed as 1:*

Lower lip . . . . .	8,448
Tongue . . . . .	1,232
Rest of mouth and fauces . . . . .	264
Esophagus . . . . .	242
Stomach . . . . .	572
Intestines . . . . .	1
Rectum and anus . . . . .	396
Skin of the face . . . . .	264
Hands . . . . .	22
Surfaces covered with clothing . . . . .	4
Vulva . . . . .	264
Vagina . . . . .	61
Cervix uteri . . . . .	5,776

This shows that, in proportion to its area, the liability of the prolabium of the lower lip to cancer is 8,448 times greater than a similar area of intestine, while that of the tongue is 1,232, of the stomach 572, and of the anus and rectum 396, the rest of the intestine being only 1. The liability of the face is 264, while that of the covered portions of the body is only 4.

It has been conjectured by very eminent scientific men that cancer is a mere product of ordinary irritation acting upon epithelial tissue or upon certain masses of embryonic tissue enveloped in the body and accidentally left over undeveloped from the fetal state, and that primary cancer attacks organs in proportion to the irritations to which they are subjected. There is a certain plausibility to this theory, but in fact it has never been proved that cancer has ever thus originated in a single instance; and, furthermore, the frequency of cancer is far from being proportioned to the amount of irritation in each organ.

There is one organ which is rebellious to every theory yet devised, my own included, and that is the Schneiderian membrane of the nose. It is extremely exposed to irritation and inflammation, and also to the reception of external germs of every kind, and yet it is rarely attacked with cancer. It is an organ standing by itself, so to speak, and possessing an exemption from attack which at present is unexplained.

Now, gentlemen, though the facts I have collected and laid before you point strongly to a probable cancer microbe, I wish you to understand that they only prove a probability, and not a certainty. Science is exacting. Before we can say that carcinoma is certainly caused by a germ, the following conditions must be fulfilled:

1. A microscopist must see the microbe.
2. He must obtain a pure culture of it.
3. He must reproduce the disease by inoculating the pure culture successfully into some animal. This has not yet been accomplished, but you and I may, nevertheless, observe the bearing

of clinical facts and note the probability where demonstration is not yet possible.

This probability brings with it important practical suggestions. If cancer is imported from without the body its invasion may often be prevented. In the breast, for instance, which furnished us with 1,232 cases, every germ must enter by the nipple, and it would not be difficult to prevent that. Bacteriologists find that a simple plug of cotton in their test tubes shuts out every foreign microbe. It would be easy to construct small concave cotton compresses, which could be worn as protectives on the breast. If desired, the cotton could be slightly dampened with glycerine to cause spores to adhere securely to the fibres, so that movements of the clothing could not cause them to sift through to the nipple. Additional security might be had by a thin rubber cap outside the cotton.

The stomach cannot be guarded from the entrance of microbes, but by attention to a healthy, moderate diet it may be kept in a condition to digest perfectly and to destroy most of the spores reaching it.

The cervix uteri can be cured of its dangerous abrasions, which probably furnish a nidus to the spores, and thus prevent it from becoming the seat of cancer. So in all parts of the body, such as the lips, the tongue, the gums, the anus, etc. If there are cancer spores in existence, cleanliness and careful preservation of the health and integrity of the surfaces will shut out the germs from the tissues which they are liable to attack.

You see, therefore, that I have a practical reason for wishing you to consider this subject, and that, acting wisely on the probability discovered, you may hope to prevent, in many cases, the onset of this disease.

No. 6 Sixteenth street, Chicago.

## MEDICAL PROGRESS.

**FIBRINOUS MEMBRANES WITHIN THE SPINAL CANAL.**—DR. JOSEPH WIGGLESWORTH reports three cases of general paralysis in which he found, *post mortem*, fibrinous membranes in connection with the spinal cord. In the first case the membrane was from one to two lines in thickness and was found lying upon the external surface of the dura mater on its posterior aspect. It extended from the third to the seventh dorsal vertebra and was attached both to the dura mater and to the walls of the spinal canal.

In the second case the membrane was similar to the foregoing one. In the third case it extended from the lower cervical to the lower dorsal region and involved the roots of some of the spinal nerves. It was everywhere coherent and

could be detached as a separate membrane. The three membranes were all *external* to the dura mater, in which respect they differ from the similar formations which are frequently discovered in the cranium, especially in post mortems of the insane. Dr. Wigglesworth believes that the membranes described are the result of a hæmorrhagic effusion within the spinal canal; that an inflammatory process is not concerned in their formation, and that they would be discovered much more frequently if sought. In the third case he suspected the presence of the membranes before the death of the patient, on account of the symptoms of irritation of the spinal nerves which existed, to wit: retraction of the head and rigidity of the extremities.—*British Medical Journal*, September 21, 1889.

**MORPHOLOGY AND PATHOLOGY OF NERVE TERMINATIONS IN MUSCLE.**—Before the Paris Academy of Sciences, October 7th, Messrs. BABE and MARINESCO reported their studies and experiments in the direction above indicated. The following is a brief *résumé*:

A modification of histological technique has enabled them to enter into an extensive consideration of nerve terminations in muscle. In examining a terminal plaque of the lizard with a strong apochromatic homogeneous immersion lens they observed two substances in the last segment of the axis cylinder. One is darkly and strongly colored by gold and stretches out in a network; the other, paler, of a fundamental character, seems associated with the pale substance of the plaque. The sheath of Schwann, spreading out, covers the plaque and becomes continuous with the sarcolemma. In the plaque the dark substance forms many sinuous ramifications communicating in arcades and possessing lateral branches terminating in crosses. In this substance exist many small rounded nuclei. It appears that the dark substance is continuous throughout the plaque by the paler material which surrounds it. In the normal state fine lateral branches of the dark substance are rarely seen entering distant nuclei of the sarcolemma while certain fine prolongations of the periphery of the fundamental material enter the intimate structure of the muscle. In man the structure of the plaque is comparatively simpler.

By cutting the sciatic nerve of the lizard we have determined an excessive atrophy of the muscle nerves and of the plaques, a breaking up of the network of dark substance, and a disappearance of the nuclei. We have repeated these experiments upon the rabbit on a very wide scale. Thirty-six hours after section of the sciatic nerve the lesion is more pronounced in the terminations than in the small peripheral muscle nerves. It consists of a nearly total disappearance of the dark network. In place of the ramifications dark

iform cellules are seen. The fundamental substance and the fundamental nuclei are visible. These nuclei are swollen, increased in number, usually rounded, and have a fine annular zone about them.

Most of the lesions found in maladies of the nervous and muscular systems correspond in general with the lesions experimentally produced. Thus, in simple muscular atrophy an atrophy of the plaques is found, sometimes with proliferation of the nuclei. In hypertrophy of certain muscles as in Thomsen's disease there is uniform hypertrophy of the dark substance. In typhoid fever there is found a simplification of the terminal plaque, and often the peripheral portion of the terminal fibre is replaced by a very fine filament. In the pseudo-hypertrophy of adults we have noted a disappearance of the dark portion not only of the plaque, but often also of the terminal perannular segments. At the same time there often exists a proliferation of the fundamental nuclei. In a case of lateral amyotrophic sclerosis the terminal fibres and the plaques were extensively atrophied. In the multiple neuritis of Leyden we have in general determined the existence of the same conditions, but at the same time the signs of a new formation are seen, and sometimes even a proliferation of the nuclei of the plaque.—*Revue Médicale*, October 9, 1889.

#### METHYL CHLORIDE AS A LOCAL ANÆSTHETIC.

DR. ERNST FEIBES, in a recent number of the *Prüfender klinische Wochenschrift*, draws attention to the extensive and successful use in the Paris hospitals of methyl chloride as a local anæsthetic. Methyl chloride ( $\text{CH}_2\text{Cl}_2$ ) is a colorless, easily liquefied gas, with an odor resembling that of ether and chloroform. The readiness with which the gas liquefies adapts it for convenient use, as it can be stored in a siphon, or in a bottle of any shape specially constructed to conduct heat badly. It may be applied to any surface directly from the siphon, or as a spray, but this method is objectionable, owing to the anæsthetized area not being in most cases sufficiently circumscribed. Bailly describes the following method, which he calls "stypage." Tampons composed of cotton wool, surrounded by a layer of flock-silk and then covered with thin silk, are saturated with methyl chloride, and applied to the part by means of wooden or ebonite holders. After contact for some seconds the part gets pale and anæmic, and diminishes in sensitiveness. If the tampon be then removed there is marked reaction, shown by congestion and slight itching; but if the application be continued for a short time longer (a few seconds) the skin assumes a white, dried, parchment-like appearance. This is the time to operate. If you proceed further superficial necrosis may result. The application is sometimes succeeded by itching and an urticaria-like eruption. It is employed in

all kinds of small operations—circumcision, opening abscesses, and in neuralgia, lumbago, muscular pains, gout, etc. In scraping lupus it is best applied by means of a camel-hair brush, as special parts can then be anæsthetized with perfect precision.—*British Medical Journal*.

#### TREATMENT OF PERTUSSIS WITH RESORCIN.

—DR. JUSTUS ANDEER reports quite remarkable results in the treatment of whooping-cough with resorcin. In a child of 7 years, on the second day after resorcin was prescribed, there was great improvement in the symptoms, and sleep at night was much less disturbed. In ten days, the cough had disappeared. With five other children the effects were even more pronounced, all being cured within a week. An infant of 6 months with vomiting after each paroxysm of coughing, was relieved by the second dose, and in five days the cough ceased. In the latter case, Dr. Andeer used a  $\frac{1}{2}$  per cent. solution in sweetened water given from the nursing bottle. In the former cases, he gave a 2 per cent. solution in water, of which half a wineglassful was administered four times daily, with directions that part should be used as a gargle, the remainder swallowed. He does not think that inhalations, or painting of the pharynx, with this solution, possess any advantages over this simple method.—*Centralblatt für medicinischen Wissenschaften*.—*Medical News*.

**TREATMENT OF CHRONIC CATARRH OF THE BLADDER.**—DR. L. FREY, in the *Centralblatt für Chirurg.* of August 17, claims that iodoform is especially suited for the treatment of chronic catarrh of the bladder, on account of its antiseptic, analgesic, and deodorizing properties.

The bladder should first be cleansed by a douche of warm water, and then a tablespoonful of the following, in a pint of warm water, injected into it:

R. Iodoform . . . . .	50 parts.
Glycerine . . . . .	40 "
Distilled water . . . . .	10 "
Tragacanth . . . . .	$\frac{1}{4}$ part.

m.

These injections should be repeated every third day. Three or four will usually effect a complete cure.

Dr. Mosetig-Moorhof has treated twenty-three cases in this way, all of which were cured. No symptoms of intoxication from the drug were observed.—*Medical Age*.

**QUININE IN PREGNANCY.**—DR. E. A. G. DOYLE, Trinidad, W. I., finds that in the West Indies, where malarial fevers are common, abortion often results from the administration of quinine, writers entertaining an opposite opinion to the contrary notwithstanding. He has studied the question in all its bearings and is convinced that it is the quinine and not the fever that occasions the abortion.—*Brit. Med. Jour.*, September 31, 1889.

PHTHISIS AND TUBERCULOSIS.

It seems that many of the enthusiasts of the microbic origin of disease, accepting the demonstrations of Koch on the origin of tuberculosis, would explain all the symptoms of pulmonary phthisis by the action of the same fungus. In tubercular disease in other parts of the body, such, for instance, as the large joints, the manifestations are quite different from tubercular disease of the lungs. There is no hectic, however great the emaciation, until the joint or large peri-articular tubercular abscesses are opened and infected with pyogenic bacteria. This ought to draw attention to the fact that phthisis is not a simple disease.

In the examination of sputa from tubercular patients, every one has noticed the abundance of micrococci and non-tubercular bacilli. These observations have lately been attested by culture experiments. The tubercular nodules are for a long time free from pyogenic infection, and the inoculation of gelatine in these early cases from isolated tubercular nodules, whether degenerated or not, is without result, as the bacillus of tuberculosis does not grow on gelatine. When, however, the disease has advanced farther, the infection of the avascular tubercular nodule follows as the result of a capillary bronchitis or accidental infection, and night sweats and other symptoms of sepsis begin. Then the cultures show numerous colonies of pyogenic bacteria in the region of

the tubercular nodules. Thus is established a condition resembling multiple abscess of the lung accompanied as a natural consequence with suppurative bronchitis. With the initiation of the pyogenic infection, the symptoms take on a graver character. Before there has been loss of strength from imperfect aeration of the blood and loaded action of the heart, now there is prostration from hyperexia, loss of appetite, night sweats and other results of sepsis. The dangers from pyogenic infection of the tubercular lung is scarcely less than that of the tubercular joint. This latter danger surgeons have long recognized. To be sure, the drainage of the lung is more complete and regular than that of any joint, so that there is less pronounced toxæmia.

The indications for treatment must be based upon a careful study of the conditions of parasitism. Until there is some form of medication which affects materially tubercular disease in joints or superficial lymph glands, there can scarcely be a satisfactory medication for tubercular disease of the lung. The administration of gases, hot or cold, seems like the application of a mad stone—irrational and irrelevant. When septic infection of the tubercular lung has taken place, the treatment cannot differ from that of septic infection elsewhere. The utter hopelessness of internal medication in such cases has been long recognized. There is nothing to be thought of which will benefit the patient except drainage, rest and food.

The proper indications for treatment point to the prevention first of tubercular infection, and when that is recognized, to the prevention of pyogenic infection of the tubercular lung. It seems *a priori* probable, as experience has shown it is possible, for tuberculosis of the lung, like tuberculosis of the joint, to remain in a dormant condition for half a lifetime, or even to disappear entirely under favorable conditions.

Here, then, is the climatic treatment of the tubercular lung disease. Put the patient in a dustless, and therefore aseptic atmosphere, and you have provided the most rational treatment. It is an autiseptic dressing to the open tubercular lung. The outdoor treatment of phthisis, or septic tuberculosis of the lung, long ago brought to popular notice by Felix Oswald, is also the rational treatment in this last and least hopeful stage of the disease.

## CHILDREN AND THEIR TREATMENT,

Although the subject of the Treatment of the Diseases of Children is rapidly becoming one deemed worthy of careful consideration, yet there remains much room for more rapid improvement in regard to their discipline and the proper understanding of their needs, etc. Unfortunately, those who are entrusted with the training of the fathers and mothers of the future are rarely selected for their amiability, or capability of treating their little charges in a proper way.

This remark applies equally to parents and to teachers. Even among those who may be regarded as fitted by education and mental refinement for the care of children, it is constantly observed that there is an utter want of information upon many points in relation to the young, which frequently gives rise to very injudicious, even injurious treatment. Popular lectures can not deal with several of these points, and hence it becomes the duty of the physician to so instruct parents and teachers that they may do no wrong to the innocents in their care. Perhaps the one point upon which the most ignorance is displayed is the needed attention to the urinary apparatus. Incontinence of urine, a very common affliction of the young, almost invariably is regarded and treated as the result of laziness or even filthiness, and the unhappy sufferer is in many cases treated most barbarously to break him or her of the habit. It has happened that medical men who have no excuse save ignorance to err in this matter, have assured the parents that it was solely due to carelessness, etc., and have been the means of the infliction of discipline at which the soul shudders. Every physician who reads this should carefully think over the matter, and see whether he or she has erred in such a case. Were parents instructed that this is a misfortune not a fault, children who are thus troubled would at once be placed under medical treatment, and cured rather than be disgraced or heart-broken by shame and unmerited punishment.

This affection assumes another phase when the child so afflicted suffers the peculiar agony of strangury when denied the privilege of retiring when the call is imperative. Unfortunately, owing to the trickery of a few, all have to suffer. It should suffice if the parents inform the teacher of this condition of the child, and a request to

retire should at once be honored. In some cases on the contrary, in place of strangury, the child when refused, at once loses control of the sphincter, and the contents of the bladder are emptied into the clothing. Either is extremely annoying to the child and liable to result in permanent injury.

Another affection incident to childhood is "night terrors." In many instances, these two are associated. Equally with the bladder trouble, has this affection been neglected or misunderstood. The child is regarded as wilfully perverse, or as having fallen into a bad habit, and is punished in a variety of ways according to the ingenuity of its "care takers!" We had better say "persecutors." Now if every physician would impress upon the mothers in his practice what is meant by "night terrors," no doubt many such cases would be recognized and placed under the proper treatment. There is reason to believe that in some cases, this affliction is liable to end in some form of dementia. For this reason also it is imperative that it should be attended to as early as possible and thus prevent so disastrous a termination.

In conclusion, while the profession are seeking all kinds of specialties at which to devote themselves, let all seek to inform themselves upon these very important subjects, with the assurance that thus they will truly be doing the work of "physicians."

## THE AMERICAN ACADEMY OF MEDICINE.

The recent meeting of the American Academy of Medicine, held in Chicago on the 13th and 14th of November, was the first one ever held in the West. Established at Philadelphia during the session of the Centennial International Medical Congress in 1876, this Association has since that date been earnestly at work to promote some of the most important interests of the medical profession. Its immediate objects, as stated in its Constitution, are to encourage young men to pursue regular courses of study in classical and scientific institutions before entering upon the study of medicine; to extend the bounds of medical science; to elevate the profession; to relieve human suffering, and to prevent disease. As was well said by a former president of the Academy, DR. FRANK H. HAMILTON, the Society seeks "to

remedy a great and universally admitted evil, namely, imperfect preparation for the study of medicine and its almost inevitable sequence, imperfect qualification on the part of those who are admitted to practice." In pointing out the available means for accomplishing this purpose, Dr. Hamilton said that the Society should labor to create a healthy public sentiment which shall, in a measure, influence medical colleges and medical men; and that, most of all, it should strive to create a sound sentiment among the young men who contemplate the study of medicine, and who should have clearly pointed out to them the most valuable means of enlarging their future fields of usefulness as practitioners. The Academy is not intended as a substitute for any other association of medical men, but as supplemental to all organizations which have for their object the uplifting of the profession and the enlargement of its field of useful endeavor.

The present meeting was an occasion of much interest. The addresses were of a very high order of merit, and some of them, especially that of the President, DR. LEARTUS CONNOR, abounded in statistical facts that cannot fail to be of the greatest interest to medical men throughout the country.

#### EDITORIAL NOTES.

##### HOME.

THE JOHN CRERAR LIBRARY.—The will of the late John Crerar was admitted to probate in the City of Chicago on the 14th inst. After the bequest of over a million of dollars to various religious, literary and charitable institutions, and to many personal friends, he also provides for the creation and maintenance of a free public library to be located in the South Division of the city. The sum appropriated for this purpose is estimated at over two millions of dollars. The execution of this trust is committed to a Board consisting of men singularly fitted for the work—and the wishes of the donor, under such management, will surely be realized. It is to be hoped that with such ample means at its command, the board of management will not only develop a model library for the public, but that ample provision will also be made for the several professions as well. If this shall be done, in addition to the magnificent reference library which was the

noble benefaction of the late Walter Newberry, Chicago, may soon become a literary centre, the advantages of which literary men will be quick to appreciate.

PUBLIC HEALTH MATTERS IN DETROIT.—Dr. Samuel P. Duffield, Secretary of the Detroit Board of Health, informs us that the State Board recently included typhoid fever as a disease dangerous to the public health and stated that according to the law it should be reported to the Health Officer. As there were certain points as to whether houses should be placarded or not, etc., the Detroit Board of Health held a session pursuant to a call from the President, Wm. Brodie, M.D., and the Board directed the following circular to be issued:

##### OFFICE OF THE BOARD OF HEALTH.

DETROIT, OCTOBER 15, 1889.

*Dear Doctor:*—Under the law requiring contagious and infectious diseases to be reported to the Board of Health, it is desirable that this Board be advised as follows:

1. Is typhoid fever in your opinion CONTAGIOUS?
2. Is typhoid fever in your opinion infectious?
3. Is typhoid fever in your opinion both contagious and infectious?
4. If typhoid fever is either infectious or both contagious and infectious, do you advise that although the law requires such diseases to be reported to the Health Office, that it should also be placarded as in small-pox, scarlet fever and diphtheria?

By promptly answering, and confining your replies to the above questions, and if possible attending the adjourned meeting of this Board in the Mayor's office at 7:30 P.M., Saturday, October 19, you will confer a favor upon the Board of Health.

By order of the Board.

WM. BRODIE, M.D., President.

SAMUEL P. DUFFIELD, M.D., Secretary.

There were 89 answers to 450 circulars sent out, and answers were as follows: Contagious: No, 60; yes, 26; in doubt, 5. Infectious: No, 14; yes, 74. Both contagious and infectious: No, 54; yes, 19; in doubt, 5. Placard: No, 69; yes, 20.

On the basis of these figures the Board directed the Secretary to notify the profession that the cases must according to law be reported, but that it was not necessary to have the house placarded, etc.

The form recommended by the United States Baggage Masters' Protective Association was endorsed by the Board. This form compels the undertaker to faithfully do his duty and swear to the same having been performed.

MEDICAL SOCIETY OF THE STATE OF WASHINGTON.—In response to a call by the President

of the Territorial Medical Society, there was a largely attended meeting of the profession at Tacoma, October 21st and 22d. The Territorial Society, as such, adjourned *sine die*. The formation of a State Society was then proceeded with, and the following officers were elected: President, Edward L. Smith, Seattle; First Vice-President, J. S. Winternute, Tacoma; Second Vice-President, M. Pietrzycki, Dayton; Treasurer, H. S. Willison, Port Townsend; Secretary, C. L. Flannigan, Olympia; Board of Censors: Drs. Shaver, Heg, Crump, Boswell and Essig; Board of Trustees: Drs. Van Zandt, Van Buren, Merrick, Libby and Marion. The regular standing committees were also appointed. There are about sixty-five charter members of the Society. The next meeting will be held at Spokane Falls on the second Wednesday in May, 1890.

DISTRICT MEDICAL SOCIETY OF CENTRAL ILLINOIS.—The fourteenth semi-annual meeting of this Society was held at Decatur on the 12th inst., with a large attendance, over 100 physicians being present. Dr. Rauch, of the State Board of Health addressed the society briefly in the evening, on "City and Country Sanitation and its Relation to Contagious Diseases."

#### FOREIGN.

BERLINERS EATING HORSE MEAT.—A dispatch from London says that the consumption of horse meat in lieu of beef is daily increasing in Berlin, and it has become almost impossible for the butchers to procure sufficient genuine beef to supply the demand of those who are able to pay the almost fabulous price which that commodity commands.

FRENCH PHYSICIANS, it seems, feel the pulse of the people of France in more ways than one. Of the 557 members returned at the recent general elections to serve in the French Chamber of Deputies, 48 are doctors of medicine, 4 are druggists, 1 is a dentist and 1 a veterinarian.

THE late Father Damien, who died in the leper settlement at Molokai, Sandwich Islands, will be succeeded by his brother.

THE SCIENTIFIC GRANTS OF THE BRITISH MEDICAL ASSOCIATION.—The following additional grants have been made by the Council in accordance with the recommendation of the Scientific Grants Committee: Mr. Hankin £50 to con-

tinue his investigations into the nature of an albuminose that has been obtained from anthrax cultures under certain conditions; Dr. R. Kirk £10 for a research on alcaptonuria and on the distinction between albumen and mucin in the urine, and some other points in connection with proteids in that fluid; Dr. J. R. Bradford £15 for some experiments on the action of the cortex cerebri on the vaso-motor system; Dr. H. A. Ashdown £10 for a continued research upon absorption from the bladder.

THE MEDICAL PROFESSION AND TEMPERANCE.—The *British Medical Journal* says: An unusually large number of important temperance conferences have been held recently, including a National Temperance Congress at Birmingham. It is significant of the lively interest taken by members of the profession of medicine in the temperance movement that at Birmingham two metropolitan physicians and at Norwich a metropolitan physician and a distinguished provincial surgeon took a prominent part, while at Glasgow a leading place in the proceedings was assigned to the assistant of one of the university medical professors. A public meeting at Birmingham was addressed by several provincial members of our Association. The British Medical Temperance Association numbers over 400 members, all abstainers.

IS MAN LEFT-LEGGED?—Dr. W. K. Sibley read a paper before the British Association in which he argued that man was naturally left-legged. Standing working with the right hand, there was a tendency to balance on the left leg. Race paths were nearly always made for running in circles to the right, and the majority of movements (such as dancing, running, etc.) were more readily performed to the right. In walking, it was more natural to bear to the right; crowds as well as individuals did so. Troops started off with the left foot; the left foot was placed in the stirrup or step of the bicycle in mounting; the left foot was the one from which a man took off in jumping. From measurements made by Dr. Garson of the skeletons of the two legs, in 54.3 per cent. the left leg was the longer, and in 35.8 the right. From measurements of 200 pairs of feet, it was found that in 44 per cent. the left, and in 21.5 the right, was longer, while in 34.5 they were equal.—*Medical Record*.

## TOPICS OF THE WEEK.

## THE ITALIAN PREMIER ON STATE MEDICINE.

In his great speech at Palermo on the 14th of October, Signor Crispi gave special prominence to what his administration had effected for the sanitary rehabilitation of Italy. "For four years," he said, "there had weighed on Italians the incubus of an epidemic"—cholera, to wit—"which, besides physical suffering and material loss had induced a moral disturbance, inevitable, perhaps, in a country where hygienic education was still so primitive and so sporadic. It was a prime necessity, therefore, to proceed at once to the sanitary rehabilitation of the State, and we made provision accordingly. We addressed ourselves first to the minds of men, and we prevailed on them to look the enemy in the face as the principal means of overcoming it. With anxious and systematic care we took the sting from present evils, and then we reconstructed laws to obviate their recurrence. Sanitary provisions should impose on the freedom of the individual no restrictions but such as are required for the safeguard of the lives of others. Personal hygiene is on that account one of those salutary measures which we are entitled to exact." In cognate spirit the municipal services were unified and at the same time reformed throughout the Peninsula; "while," continued Signor Crispi, "we modified the constitution of the Sanitary Councils, so as to insure an earnest and an unremitting surveillance over the public health. We restored to its proper centre—the Home Office—the direction of the seaboard lazarettos, and by furnishing the chief ports of the kingdom with the means of precaution and defence, we established an outpost system to make head against the importation of disease. By decree and by law of favor (*legge di favore*), we assisted the minor communes in carrying out their sanitary rehabilitation—an opportunity of which already more than three hundred have taken advantage. By a modification and extension of the Bill, enacted for the benefit of Naples, the application of which to themselves was craved by some sixty communes, by considerably evoking and approving plans of house-reconstruction (*piani regolatori*) we have brought to the great cities the blessings of effective sanitation." Nor have more strictly medical reforms been neglected. "We have reconstituted," said Signor Crispi, "the whole vaccination service; we have revised the Pharmacopœia; and on the frontier towns, as a safeguard against epizootic invasion, we have brought up the veterinary stations to military efficiency. We have wrought, in a word, the practical consummation of that sanitary code whose fundamental idea will prove not the least title to the love and veneration long earned from all Italians—whether surviving comrades, or of future generations—by that soldier of science, of fatherland, and of freedom, Agostino Bertani. Thus we may pronounce ourselves as on the true path of that sanitary redemption for which, not less than the political, Italy was yearning—a redemption of equal necessity, and certainly not less of a blessing. An Italy sound in a physical sense will yield us those vigorous arms which will ferti-

lize her the best—those hardy constitutions which as living ramparts will prove her strongest safeguard." The "youngest of the Great Powers" is to be congratulated on the enlightened legislation set forth in these eloquent periods. It will henceforth be her duty to develop, as well as maintain, the sanitary reforms she has effected, and to justify in this respect the position she has earned in the European State-system.—*Lancet*.

## WORK KILLS NO MAN.

From the Harveian Oration delivered at the Royal College of Physicians, October 18, 1889, by J. E. POLLACK, M.D., F.R.C.P., we quote the following concluding sentences:

I need not say to such an audience as this that *work*—the due exercise of every function given to us—kills no man and shortens no life. The causes are to be found in what is called our extended civilization. We are no longer traders to one country, nor for one or two commodities; but the telegraph has introduced us into a widened sphere, and our merchants have investments in every climate, and enter on risks of a kind so varied that the knowledge of no one man is sufficient to grasp it. Hence there are the anxieties of extended speculation, and a necessary want of the perfect understanding of each. The knowledge of one kind of trade was formerly "power," and led to prosperity; now we are playing games with all the world. Those who are present know well what part of the organism it is which generally fails under such pressure. The public say it is *brain*, but we know that it is *heart*—the motor power which Harvey studied, although, perhaps, he did not foresee to what pressure a modern civilization and struggle would subject it.

I have spoken but of the trading class and the speculative class, but all classes of society should learn to counteract in themselves the depressing agents of excessive worry, and to beware of the race which, once entered on, may exceed the best of our powers and ruin the machine.

## RESULTS OF VACCINATION.

The opponents of vaccination in England, says *Science*, have of late been more active than ever; and as a result of their activity, a Royal Commissioner has been appointed, whose duty it shall be to make a full investigation of the whole subject and submit a report thereon. Friends of vaccination should welcome such an inquiry, as the method stands upon such a firm foundation of facts as to be able to stand the most searching examination. If it has not accomplished all that is claimed for it, the failure is due to insufficient or inefficient performance of the operation, and the sooner such abuse of it is made public the better. It is a rather remarkable coincidence that just at this time events should transpire at Sheffield, Eng., which show the value of vaccination. Small-pox has recently been very prevalent in that city. In a population of about 320,000 there have been 6,088 cases of the disease, of which number 590 proved fatal. Dr. Barry, who has made a report to the local Government Board, finds that the attack rate of the vaccinated

children under 10 was five in 1,000; of the unvaccinated of the same age, 101 in 1,000. The death-rates for the same classes were respectively .09 and .44. In every 1,000,000 of those twice vaccinated there were eight deaths; once vaccinated, 100 deaths; and unvaccinated, 5,100 deaths.—*The Druggists' Gazette*.

#### THE DEATH OF ISAAC E. TAYLOR, M.D.

We have received from the New York State Medical Association the following transcript from its minutes :

The Council of the New York State Medical Association sadly records its unfeigned sorrow for the loss of a valued founder, fellow and late president, endeared by his personal qualities as he was admired for his scientific attainments.

An illustrious name is transferred from the active list to the roll of honor of those who have bravely borne themselves in the foremost rank and fallen triumphantly.

Untiring in industry, wise in counsel, affectionate in friendship, steadfast in religious faith, beloved by his associates and revered by the profession which acknowledged him as one of its leaders, Isaac E. Taylor lived an example for emulation by his survivors and successors, and rests from his labor, leaving a reputation unassailed by enmity and beyond the reach of jealousy.

By the Council,

JOHN G. ORTON, M.D., President.

E. D. FERGUSON, M.D., Secretary.

#### ANGLO-AMERICAN VIENNA MEDICAL ASSOCIATION.

A meeting of British and American physicians was held recently at Vienna to consider the question of establishing an association for the purpose of furnishing all needed information to English-speaking medical men coming to study in Vienna. A large proportion of those now in the city were present, and it was resolved to start such an association, under the title of the "Anglo-American Vienna Medical Association." A committee of management was appointed, whose chief duty will be to supply information to newcomers on their arrival as to matriculation, medical courses, lodgings, etc., and, when necessary, to call meetings of the Association. The committee, on the occurrence of vacancies in their number through members leaving Vienna, will fill these up as soon as possible. The office of the Association will be at No. 12 Landesgerichts Strasse. It was agreed that membership should be open to any British or American physician or medical student on payment of an entrance fee of one guilder. Letters of inquiry, addressed to the President or Secretary, will at once receive attention.—*The Lancet*.

#### IMMUNITY AGAINST ANTHRAX.

The question of immunity against infectious diseases is the question of the day. In many bacteriological laboratories experimenters are working at that subject with varying success. Since Pasteur's first publication on preventive inoculation against cholera of fowl, *rouget*, anthrax and rabies, numerous experimenters have confirmed his statements, and the practical value of such preventive inoculations has now been abundantly proved.

The whole subject, however, is still in its infancy, for the way in which immunity is produced—the mechanism of immunity, to borrow Professor Bouchard's happy expression—is by no means clear. M. Pasteur, two years ago, in a letter to M. Duclaux, suggested that immunity against rabies in patients who had undergone his preventive treatment might be due to a chemical vaccinating substance secreted by the microorganism of rabies. There are many facts in favor of this theory, though unfortunately its truth has never been conclusively demonstrated.

In 1887, Messrs. Salmon and Smith showed that if a culture of the bacillus of hog cholera, after being sterilized by heat (58° C.), was injected into an animal, the latter acquired an artificial immunity against the bacillus of hog cholera, so that when the living microorganisms were injected they produced no symptoms. The demonstration of chemical vaccinating substances was not altogether satisfactory until Charrin, in the same year, proved that the introduction of a heated and filtered culture of the bacillus pyocyaneus protected rabbits against the inoculation of the living bacillus pyocyaneus. Roux and Chamberland shortly afterwards proved this to be true for malignant oedema, whilst Chantemesse and Vidal were able, by using a similar method, to protect mice against the evil effects of the typhoid bacillus. The experiments of the lamented Dr. Wooldridge on anthrax are also of the greatest importance, as showing the protective power of chemical substances.

The latest contribution to our knowledge of immunity is the paper by MR. E. H. HANKIN, in this week's number of the *Journal*. Mr. Hankin claims to have prepared from the cultures of anthrax an albumose which, when injected into mice or rabbits, protects these animals against the action of the anthrax bacillus. Mr. Hankin's experiments were made under the guidance of Professor Koch, at Berlin and, as far as they go, appear to warrant us in thinking that he has discovered an improved method of vaccinating against anthrax. We must wait for a full account of all his experiments, to enable us to form an opinion as to the practical value of his work, but its scientific interest will be at once evident.

Mr. Hankin concludes his paper by a series of conclusions which are rather suggested than proved by the facts he has published up to the present date. As his paper is only a preliminary account of his investigations, we must reserve further remarks until we are in possession of all the data on which his conclusions are based.—Editorial in *British Med. Journal*.

#### THE HOSPITAL BULLETIN

The trustees of the Johns Hopkins Hospital have authorized the issue of a monthly publication to be known as the *Hospital Bulletin*. It will contain announcements of courses of lectures, programmes of clinical and pathological study, details of hospital and dispensary practice, abstracts of papers read and other proceedings of the Medical Society of the Hospital, reports of lectures and all other matters of general interest in connection with the work of the Hospital. Nine numbers will be issued annually. The subscription price will be \$1. Subscriptions may be sent to the publication agency of the Johns Hopkins University, Baltimore, Md.—*Maryland Medical Journal*.

## PRACTICAL NOTES.

### THE INFLUENCE OF THE NERVOUS SYSTEM ON RENAL FUNCTION.

The *Lancet* gives an abstract of Dr. Francesco Spallitta's experiments, made with the view of ascertaining whether the effects produced on the renal secretion by lesions of the medulla oblongata are due, as held by Ustimowitsch, Heidenhain and B. Sachs, to the alteration of the blood-pressure caused by the lesion, or, as supposed by Eckhard, to some morbid change in the innervation of the kidney. The plan adopted was to cut through the spinal cord at various levels, and to watch the effect upon the secretion of urine.

In order to be certain that the urine found in the bladder at the necropsy was secreted after the spinal cord had been cut, a solution of iodide of potassium was injected under the skin after the operation, and the urine tested for iodine. The results obtained were as follows:

1. Lesions of the cord at the base of the first dorsal vertebra produce no changes in the renal secretion.
2. Sections at the seventh cervical and first dorsal vertebra permit the continuance of the secretion.
3. Sections at the sixth, fifth or fourth cervical vertebra allow the secretion to continue, but cause the urine to contain a certain amount of albumen.
4. Sections at the third or fourth cervical vertebra arrest the secretion altogether.
5. Electrical stimuli applied to the cord in the cervical region arrest the secretion entirely.

The theory which seems to Dr. Spallitta to accord best with these facts is, that the effect on the renal secretion of lesions of the cord is mainly due to the destruction of special nervous fibrillæ existing in the cord which govern the function of secretion of urine.—*Canada Lancet*.

### TREATMENT OF SPRAINS.

It may be observed that a sprain is frequently treated with a liniment advised by physicians. It is, indeed, painful to see a physician writing a prescription for a sprain. There are but two indications in the treatment of sprains: 1. To provoke rapid absorption of the fluid effused around and within the joint; and 2, to favor cicatrization of the torn parts by immobilizing the articulation. Now, the modes of treatment hitherto in vogue do not fulfil these two indications. Massage would seem to present some real advantages, but it can be of little service in the case of severe sprains, and mild injuries would probably do as well under rest alone. An elastic bandage, the depressed parts being covered with a layer of cotton so as to prevent too great pressure over the prominence, and thereby causing sloughs, will meet the first indication, and by its use in procur-

ing rest it will meet the second indication. This bandage acts like massage in promoting absorption, and also secures immobility of the joint. It is of equal service in sprains complicated with rupture of points of insertion, whereas massage would be productive of harm in cases in which splinters of bone were torn away. The practice of relieving the mind of the patient by giving him something to do in the way of applying bad-smelling linaments is a pernicious one, and really shows an unprofessional or unscientific attendant.

### THE CONDITIONS OF INTRA-UTERINE INFECTION.

Infection of the fœtus before birth is a recognized fact, but it is, perhaps, too readily assumed that infective material may pass from the maternal into the foetal blood by the normal channels of embryonic nutrition. Dr. Romeo Mangeri, of Catania, believes this to be impossible. As the result of wide study of the literature of the subject and of original experiments, he has come to the conclusion that no formed elements naturally pass out of the mother's blood into the foetal circulation. Cinuabar, Indian ink, carmine, and other materials were injected into the jugular veins of animals advanced in pregnancy, but in no case could any trace of the substance employed for experiment be found in the fœtus. Passage of formed elements can only occur when the maternal placenta becomes diseased by inflammation, hæmorrhages, etc.; so that the walls of the villi are destroyed. Only under these conditions can septic or specific organisms pass from the mother into the blood of the fœtus.

### EATING BEFORE SLEEPING.

A recent writer says that the view that brain workers should go supperless to bed is not good advice. Most medical authorities of the day think it wrong. It is a fruitful source of insomnia and neurasthenia. The brain becomes exhausted by its evening work, and demands rest and refreshment of its wasted tissues, not by indigestible salads and "fried abominations," but by some nutritious, easily digested and assimilated articles. A bowl of stale bread and milk, of rice, or some other farinaceous food, with milk or hot soup, would be more to the purpose. Any of these would insure a sound night's sleep, from which the man would awaken refreshed.

### HEADACHES FROM ALCOHOL AND TOBACCO.

DR. E. LLOYD HUGHES recommends the following formula in headache from abuse of alcohol and tobacco:

R. Spir. Ammon. aromat . . . . . f ʒss.  
Spir. Chloroformi . . . . . mx.  
Aquam ad . . . . . f ʒj.  
S.—At one dose.

## SOCIETY PROCEEDINGS.

## Medical Society of the District of Columbia.

*Stated Meeting, March 27, 1889.*

DR. S. C. BUSEY, PRESIDENT PRO TEM.

DR. ROBERT T. EDES presented a specimen and history of an

## ENLARGED PROSTATE GLAND.

The patient was a man æt. 76, very corpulent, of excellent habits in early life, but of late years using a great deal of alcohol. In October, 1887, he consulted a surgeon in London for urinary trouble, and since that time has been constantly attended by a male nurse, who has used the catheter at intervals, usually of from two to three hours in the night, but sometimes considerably longer. He has had several attacks of hæmaturia, attended with fever, and in the intervals the urine has been profuse and purulent, but seldom ammoniacal. He failed gradually without any very marked new symptoms except increasing stupor but not coma, until shortly before death. After death the prostate was found greatly enlarged in all directions, and, in addition, the middle lobe stood up as a distinct tumor in front of the internal orifice of the urethra. In this neighborhood there was much congestion and ecchymosis, being probably the seat of the hæmorrhage. The urethra, through the prostate, was of full size, and an instrument could be readily passed. The ureters were somewhat dilated, and also the pelves of the kidneys. The secreting substance of the kidneys was but slightly encroached upon. The surface was somewhat granular, and they presented to the naked eye the appearance of fatty degeneration in patches.

DR. SMITH had presented a specimen some years ago resembling that reported by Dr. Edes to-night. It was an enlarged prostate and over 100 calculi were found in the bladder. An aged colored man was taken on the street with a desire to urinate, but could not. A physician passed a catheter and a profuse hæmorrhage followed. Dr. Smith was then sent for and found him suffering greatly from an inability to pass water. The bladder was distended and painful to pressure. It was with difficulty that he passed a catheter. Bloody urine was withdrawn and the bladder washed out. Some time after the man suddenly died, and at the post-mortem the prostate gland was found to be very much enlarged and there was a tear in the prostatic urethra.

DR. J. FORD THOMPSON: If the diagnosis could be made he preferred Harrison's operation. Such patients usually suffer, from time to time, from the obstruction, and there is probably some dilatation of the ureters. In such cases he would

perform the median operation, puncture the bladder and remove the middle lobe of the prostate gland; or the same result could be accomplished by epicystotomy. He thought that complete excision would have cured Dr. Edes' patient. Much smaller enlargements would obstruct the flow, and excision would be advisable.

DR. EDES: There had never been any retention of urine in the case, and the man had seldom gone more than four hours without having his urine drawn with the catheter, as he had a constant attendant for that purpose.

DR. J. FORD THOMPSON presented a limb amputated for

## ARTHRITIS OF THE RIGHT KNEE.

Sarah Pinn, æt. 12, colored: father living, mother dead, cause of death not known. The patient was well up to one year ago, when she fell and injured her right knee. After a day or so she experienced no trouble until February, 1888, when it was noticed that her right knee was somewhat larger than the left, and she also complained of pain when walking. Her knee gradually grew larger until her admission to the hospital, September 1, 1888.

Present condition: General health seems to be good and she has the appearance of being well nourished. Physical examination of knee shows it to be about as large again as normal. On palpation she complains of pain on the inner side and a little below the joint.

October 14—Complains of great pain in knee. Was given morphia sulph. daily. Slight fluctuation can be detected on outer side, just above head of fibula.

October 16—Patient was anaesthetized and an incision made over the knee joint, beginning just below the internal condyle of femur and passing anteriorly across the middle of the patella to a point corresponding on the outer side of the joint. The patella was then sawn through and the leg forcibly fixed on the thigh, which exposed the articular surfaces of the tibia and femur. The articular cartilages of the tibia were entirely gone and those of the femur so much diseased that they were removed with a saw. The internal tissues of the joint were extensively diseased and were all removed, including ligaments, leaving the posterior ligament intact. A thin slice of articular surface was removed by saw. After denuding the articular surface of the tibia the wound was irrigated with carbolic sol. 1-60. Two drainage tubes were then inserted with counter-openings above the knee externally and posteriorly. The denuded surfaces of tibia and femur were then brought in apposition and held by two silver wire sutures. After this the patella was wired together and the wound closed with six silk-worm gut sutures. The leg was then dressed antiseptically and placed in a plaster case.

October 17.—Owing to the fact that there was considerable oozing after the operation the dressings were removed and carbolized water injected to check the hæmorrhage. It was again dressed antiseptically.

October 22.—Drainage tubes removed; general condition much better, but no evidence of union between the bones.

November 1.—General condition good; is gaining flesh.

December 1.—Patient not doing so well; has two sinuses in knee which discharges bloody-looking pus. Temperature is of a hectic type.

January 1, 1889.—No evidence of union between the bones.

January 15.—Patient was anæsthetized and a semi-lunar incision made across the anterior surface of the knee just below the patella. The leg was then fixed, as in the first operation, and the softened tissue around the joint all removed with a sharp spoon. The wound was then closed with six silver wire sutures, dressed antiseptically and placed in a plaster case.

January 16.—Has been no evidence of shock; patient in good condition.

February 24.—Plaster cast removed; still no union between the bones; temperature continues to be of a hectic type.

March 10.—Is loosing flesh rapidly.

March 26.—At a consultation held the following physicians were present: Drs. Lovejoy, King, Johnston and Thompson. It was decided to amputate the limb immediately. The patient being anæsthetized, the limb was amputated just above the condyles (Long anterior flap method). The stump was dressed antiseptically and patient put in bed.

April 2.—Dressings removed; nearly all of the flap has united by first intention; general condition and appetite good.

DR. THOMPSON had referred to this case at the last meeting, and had said that he thought amputation would be necessary. At a meeting of the Consulting Staff of the Children's Hospital, held March 26, it was unanimously decided to amputate at once in order to give the girl the best chance of life. Dr. Lamb would present a section of the knee-joint at some future time.

#### Tri-State Medical Association.

*First Annual Meeting, held at Chattanooga, Tenn.,  
October 15 and 16, 1889.*

*(Concluded from page 716.)*

DR. COOPER HOLTZCLAW read a paper entitled  
REPORT OF TWO CASES OF LAPAROTOMY, WITH A  
SPECIMEN.

*Case 1.*—Female, married, æt. 20. History of

pelvic cellulitis two or three years previous, followed by ascites which was evacuated several times. Uterus immovable, tumor size of a hen's egg, to right of Douglas' cul-de-sac and in rectum, gut painful to touch and on defecation.

Diagnosis: Ovarian cystic degeneration. Laparotomy June 8, 1888. Both tubes and ovaries adherent to all contiguous tissues. As many adhesions as possible were broken up and diseased tissue removed. Recovery slow; at present date good health.

*Case 2.*—Female, æt. 19, unmarried. History: January 1, 1888, noticed small floating tumor in the right iliac region, which gradually grew larger until she was as a woman at full term; considerable dyspnea, irregular menstruation, anorexia, emaciation; xyphoid cartilage dislocated and painful; uterus normal; urine normal; heart normal but rapid and weak. Diagnosis: parovarian cyst. Laparotomy October 1, 1889. Removed large sac containing 2 gallons of fluid and colloid substance; pedicle small, short, and attached to parovary. Patient discharged on fifteenth day.

DR. J. F. LYNCH, of Chattanooga, read a

#### REPORT OF A CASE OF LAPAROTOMY.

The patient was a widow æt. 35. Had been an invalid for years. The operation was performed for pyosalpinx, which was ruptured in the attempt to break down the extensive adhesions and its contents emptied into the abdominal cavity. After the operation the abdomen became fearfully distended by an accumulation of gas in the intestines. To relieve this condition teaspoonful doses of Epsom salts were given every hour, enemata of turpentine and asafoetida were administered, and a tube passed some distance up the rectum through which numerous injections were given. Gas continued to accumulate and, having exhausted all means of relieving the distension, Dr. Lynch feared intestinal obstruction, and was preparing to operate again when, in the afternoon of the fifth day, she had a copious action from the bowels and the distension disappeared. The operation was performed under strict antiseptic precautions. The patient has entirely recovered.

These papers were discussed by Drs. G. A. Baxter, R. J. Trippe and W. C. Townes.

DR. TRIPPE related a case of ovariectomy of Dr. J. B. Cowan's. Cystic tumor of the right ovary in a woman æt. 25, single, domestic. Abdomen very much enlarged but symmetrical. Aspiration of a semi-solid, amber-colored fluid. The diagnosis of cystic tumor of the ovary was made, for which the doctors operated. A multilocular cyst of the right ovary was found, which was removed with the tube. Two of the cysts had been ruptured and it was estimated that there was 100 lbs. of fluid in the peritoneal cavity. The patient had

an uninterrupted recovery and was allowed to go out of the room in three weeks. She has remained well since and is earning her own living. He also reported a case in which he had performed laparotomy for stab-wound of the abdomen on a man æt. 38, in which the transverse colon was incised in two places. The incisions in the gut were oblique. There was an escape of faecal matter from the wounds, which were stitched with catgut. The intestines had protruded from the wound and had got in the mud, and afterwards been covered with a blanket which had been used for dogs to lie on. The exposure had been for about an hour. The incision in the abdomen was closed with a three line suture. The next day there was a temperature of  $101.5^{\circ}$ , which lasted but a short time. The man was up in two weeks.

DR. FRANK TRESTER SMITH, of Chattanooga, read a paper entitled, *Report of a Case of Persistent Pupillary Membrane*. The paper was illustrated with a drawing. No treatment was recommended.

DR. REEVES asked if the condition might not be due to the result of an inflammation?

DR. SMITH said that it was possible, but that the inflammation must have occurred *in utero*, as there was no structure other than the pupillary membrane that would leave a grayish substance on the capsule of the lens with threads running to the anterior surface of the iris and attached to the circulus iridis major, as in the case presented.

DR. MAX THORNER agreed that no treatment was indicated and no other diagnosis possible from the description of the case. He related a case which he had seen in which an operation was attempted but the result was not encouraging.

DR. JAMES E. REEVES read the original account of *Ephraim McDowell's First Ovariectomy*.

In an omnibus discussion which followed the subject of hypnotism came up and was discussed by Drs. G. W. Drake, J. M. Heard, W. C. Townes, G. A. Baxter and R. D. Boyd.

After the transaction of miscellaneous business the Association adjourned to meet again in Chattanooga, October 21, 1890.

## FOREIGN CORRESPONDENCE.

### LETTER FROM PARIS.

(FROM OUR REGULAR CORRESPONDENT.)

*Dr. Du Castel on the Treatment of Chronic Blenorrrhagia*—*M. Chauveau on Transformism in Micro-Biology*—*Dr. Clado takes up the Question Whether the Liquids contained in the Herniary Sac should contain Toxic or Irritating Matters?*

My letter in THE JOURNAL of August 3d last contains a note of Dr. Du Castel on the antiseptic treatment of blenorrrhagia in its acute stage.

I now forward another note by the same author on the treatment of chronic blenorrrhagia. This note is the summary of a clinical lecture delivered by the author at the Hôpital du Midi, and which is of some importance owing to the experience acquired by him. After having tried a great number of medications for this affection, Dr. Du Castel has been led to the following conclusions: Internal medication, so useful in acute cases, has a very contestable action on blenorrrhœa. The balsamics have appeared to be of some utility, but the mode of administration differs; it is no longer in high doses that they are administered, but in small quantity and during a long time. The veritable treatment of chronic blenorrrhagia is the local treatment. According to the experience of Dr. Du Castel, the porte-caustic of Lallemand, the topical remedies applied directly to the mucous membrane by means of the endoscopic tube, as also the medicamentous bougies and sprays, have given certain results, but which appeared to him inferior means as compared with the current methods, injections, lavages and instillations. The two first therapeutic means are chiefly indicated in acute blenorrrhagia, lavages appear more efficacious than simple injections, but they are of more difficult application. The solutions should be relatively concentrated; the caustic substances, such as the injection that bears the name of Ricord, or that of the three sulphates, are the most efficacious. As regards the antiseptic substances, they do not act so well as in acute urethritis. Of all the agents employed locally, instillations deserve the preference. As regards the solutions, those of the nitrite of silver produce a cauterization to the degree necessary to modify the mucous membrane; the strength of 1 to 50 parts often suffices. This is the method practiced by Professor Guyon which Dr. Du Castel has adopted, after having tried a great number of other means.

At a recent meeting of the Academy of Sciences M. Chauveau, the well known veterinarian, made an important communication on transformism in micro-biology, in taking, for example, the limits, the conditions and the consequences of the variability of the "bacillus anthracis." It results from the researches of the learned experimenter that, thanks to the persistence of the action of compressed oxygen on the cultures of the bacillus anthracis in course of development, one succeeds in creating races or types of less resistance than the primary bacillus, and which are particularly sensible to the influence of the attenuating agent which had procured for the bacillus its new properties. If this influence of the attenuating agent is prolonged, the new types lose the aptitude of vegetating in its contact. But, as long as the bacillus does not pass the limits of vegetability, it remains in the domain of pathogenic agents. It loses, it is true, all virulent property, but it preserves integrally the vaccinal

property and preserves it almost intact during the whole duration of its existence. These new characters are fixed and are easily entertained by culture in successive generations. Thus, in considering these types in themselves, without taking into account their origin, they may be regarded as forming one distinct species. It would not be impossible that the special types of the bacillus anthracis exist in nature with properties absolutely identical with those of the created races, and entertained in the laboratory.

In a memoir published in 1861, Prof. Verneuil emitted the idea that the liquids contained in the herniary sac should contain toxic or irritating matters. In 1867 he caused the contents of a herniary sac to be examined by Dr. Nepven, who found micrococci. At one of the sittings of the last Congress of Surgery, Dr. Clado, of Paris, took up the question. A man aged about 30 years, vigorous, and the subject of a reducible congenital hernia, was admitted into the Pitié Hospital with the signs of a strangulated hernia. He was operated on on the following day, sixteen hours after the commencement of the accidents. The temperature of the body was  $36^{\circ}$  C. at the time of the operation. Death took place one hour after. In the contents of the sac, examined immediately, there were found numerous bacteria, mobile, with which he made some cultures. These bacteria were found again the next day in the blood, the peritoneal serosity of the patient, and in the incisions made in the viscera (the spleen and the lungs). In the strangulated knuckle there were the same microbes as in the glands, the blood-vessels and lymphatics. The cultures furnished one special bacterium, which, cultivated at  $28^{\circ}$  C., proved to be inoffensive, whereas when cultivated between  $37^{\circ}$  C. and  $40^{\circ}$  C., it becomes mortal in a few hours. The inoculation of the blood of the patient produces the death of animals in a very short time. In fine, the inoculation with the serosity or with the blood of animals caused death in series. The microbe proved itself particularly pathogenic for the guinea-pig and the rabbit. In the dog it produced vomiting, inappetence, followed by complete recovery. The bacterium multiplied itself with astonishing rapidity in the organism of the animals. To explain the cause of death, particularly rapid death, in cases of hernia, nervous exhaustion was suggested, the constriction of the filaments of the great sympathetic nerve, the overdistension of the abdomen with gas, visceral congestion, particularly of the lungs, finally stercoræmia. Dr. Clado explains death in strangulated hernia by the penetration into the economy of a bacterium having for its starting point the surface of the intestine. Visceral congestions, frequently observed, are the result of the localization of the bacteria in the viscera, and particularly in the lungs. Herniary peritonitis and gen-

eralized peritonitis without opening in the intestine are the result of the migration, through the intestinal pariety, of the bacteria into the peritoneum. Dr. Clado admits that the distension of the intestinal knuckle by gas pushes these microbes into the thickness of the ulcerated mucous membrane.

A. B.

## DOMESTIC CORRESPONDENCE.

### "Professional Organization."

*To the Editor:*—Your editorial of September 28th on "Professional Organization" is not likely to be without a response from the many physicians whom it concerns. This is the age of organizations, and while every true member of the medical profession would decry an association having for its chief aim the selfish advancement of the individual or a favored few, yet we all have a right to urge that which will bring the members of our guild into closer relationship.

For many years the American Medical Association has stood, in numbers and importance, far beyond any other; but now we have new organizations which, though they may never rival the national body, are yet representative and growing larger each year. These societies, it seems to me, are midway in the large distance which lies between the American Medical and the State associations, and are composed mainly of men who are members of both.

These district societies are well organized and are sure to continue. The question to be answered is, shall their interests and that of the American Medical Association be united? That such union would be of mutual advantage seems apparent for several reasons.

1. As already suggested, a better system of collective investigation of disease could be instituted.

2. Questions which cannot fully be discussed in the American Medical Association, for want of time, could be referred to one of the branches. This could be well done where questions arise pertaining to variations of disease peculiar to certain latitudes or geographical sections.

3. THE JOURNAL of the Association would, by the adoption of some such plan as suggested in the editorial referred to, be strengthened and become even more than at present the representative national journal.

4. There would be a better union and closer fellowship among the members of the different societies, many of whom are unable to attend the American Medical Association regularly.

Possibly five branches might be formed, one in New England, one in the Middle States, another in the South, and one on the Pacific coast, while the Mississippi Valley Medical Association could

easily represent the territory implied by its name. There is strength in the very thought of such a wide-reaching organization. At the national meeting and its branches we can have each year a registration of 10,000 physicians as easily as we now have one-fifth of that number.

It seems to me that, in justice to the thousands of physicians in America, as well as for the best interests of the American Medical Association, this question should be thoroughly discussed.

Respectfully,

WM. PORTER.

St. Louis, November 12, 1889.

## BOOK REVIEWS.

**DISEASES OF WOMEN.** A Manual of Non-Surgical Gynecology Designed Especially for Students and General Practitioners. By F. H. DAVENPORT, A.B., M.D., Assistant in Gynecology, Harvard Medical School; Assistant Surgeon to the Free Hospital for Women, Boston, etc. With 105 Illustrations. Octavo, pp. xiv, 292. Philadelphia: Lea Bros. & Co. 1889.

In this modest volume the author has endeavored to set before the student the elementary principles of the methods of gynecological examination, together with the simple forms of treating the most common diseases of the pelvic organs, and to assist the general practitioner in understanding and treating the gynecological cases of his everyday practice. Surgical gynecology and pathological anatomy have been omitted, for the most part, with a view to make room for a description of many minor points which are often wanting in other works. It is not too much to say that the author has carried out his plan in an admirable manner, with the result of producing a thoroughly practical and useful work which, while it commends itself particularly to the beginner, contains much of value to the practical gynecologist; thus his chapter on "Displacements of the Uterus," which includes the methods of diagnosis, the use of the probe, and the instructions for measuring the vagina and applying pessaries, would do credit to a very much larger and more pretentious treatise. The work is certainly a very attractive one, and is of a character to encourage the hope that another and enlarged edition will soon be required.

**TRANSACTIONS OF THE LOUISIANA STATE MEDICAL SOCIETY,** held at New Orleans, April 9, 10 and 11, 1889.

The report of the work done by the Louisiana State Society for the past year speaks well for the earnestness and zeal of its members. The papers read were numerous, interesting and varied in

character. Three of the most extensive papers were read by Dr. Joseph Jones, who discussed at length the subjects of the care of the insane, the relations of quarantine to commerce and the action of antipyretics in febrile diseases. These are notable papers and deserve a careful reading. Interesting contributions to surgery were made by Dr. R. Matas on "Multiple Subperiosteal Sarcoma of Skull" and "Circular Enterorrhaphy;" by Dr. G. B. Lawrason on "Two Cases of Hysterectomy;" and by Dr. E. Souchon on "The Drilling of Capillary Holes through the Skull for the Purpose of Exploration with the Hypodermic Needle."

**SAUNDER'S QUESTION-COMPENDS, NO. 1, ESSENTIALS OF PHYSIOLOGY.** Arranged in the form of questions and answers; prepared especially for students of medicine by H. A. HARE, B.Sc., M.D., Dem. of Ther. and Instructor in Physical Diagnosis in the Univ. of Penn., etc., etc. Second edition, revised and enlarged; pp. x, 193. Philadelphia: W. B. Saunders. London: Henry Renshaw. Melbourne: Geo. Robertson & Co. 1889.

While open to many of the criticisms which assail medical compends designed for students, this little work is deserving of much praise as being a very excellent one of its class. Students no doubt often abuse themselves by doing superficial work and glossing over their real ignorance with a little of the more easily acquired knowledge; but, nevertheless, if properly used such books may be made to greatly lighten the tasks of the already overburdened under-graduate. We do not hesitate to pronounce this such a book. Not the least of its many excellencies is the admirable selection of the illustrations, which are uniformly above reproach both in accuracy of design and mechanical execution.

**TRANSACTIONS OF THE IOWA STATE MEDICAL SOCIETY.** Vol. VII, 1886-1889.

This volume of Transactions covers the work done by the Society in four years. It comprises sixty-one papers, nearly all of which may be said to be rather meagre, as may be judged by the fact that they find plenty of room in a book of only 564 pages. The work accomplished is very good as far as it goes, but the Society evidently needs tonic treatment to prevent premature decay. From such a magnificent State as Iowa it is not too much to expect the very best of work.

**PHYSICIAN'S LEISURE LIBRARY—DYSPEPSIA.** By FRANK WOODBURY, M.D. Pp. 86. Detroit: Geo. S. Davis.

This is an excellent thesis reviewing the newest knowledge that has been acquired and that is pertinent to the subject. The book is not a systematic treatise but rather a fresh, interesting and

suggestive one. Both the symptomatology and treatment are discussed. Dr. Woodbury insists upon defining dyspepsia as a general disease which is due to poisoning of the system with the products of imperfect digestion and of gastric fermentation. In the closing chapter the subject of dietetics for dyspeptics is considered.

THE AMERICAN ARMAMENTARIUM CHIRURGICUM. Imperial 8vo. 1889. New York: George Tiemann & Co.

We are in receipt of a copy of this finely printed and handsomely bound volume. It contains 862 pages, 3,400 engravings, and descriptive matter of surgical instruments and appliances. The text is fuller than is usually found in trade catalogues, and is a credit to the enterprising firm issuing it. The work is supplied to the profession at about the cost of the binding.

TRANSACTIONS OF THE AMERICAN SURGICAL ASSOCIATION. VOL. VII. Edited by J. EWING MEARS, M.D., recorder of the Association. Philadelphia, 1889.

The elegant typography and binding of this volume are fully justified by the valuable material which it contains. Fifteen articles fill the 217 pages of the book. Nine of these are chiefly or entirely devoted to the reporting of cases, and the remainder are for the most part systematic studies.

Dr. Stimson advocates the attempt to ligate separately the arteries in pedicles of abdominal growths instead of treating the stump as a whole.

An article on digital divulsion of the pylorus for cicatricial stenosis, by Dr. J. M. Barton, is instructive and timely.

Dr. McGraw, of Detroit, contributes to the history of gunshot wounds of the intestines.

Dr. Maurice H. Richardson reports upon the surgical treatment of gangrenous hernia in four cases that he observed.

The papers read before this Association are of a high order of merit, as would be expected from the *personnel* of the Society, and the present volume will be a valuable addition to the surgeon's library.

WOOD'S MEDICAL AND SURGICAL MONOGRAPHS. Vol. III, No. 3, Sept., 1889. William Wood & Co., publishers, New York.

This number contains the following excellent monographs: "Congestive Neurasthenia or Nerve Depression," by E. G. Whittle, M.D.; "The Art of Embalming," by Benj. Ward Richardson, M.D.; "The Etiology, Diagnosis and Treatment of Tuberculosis," by Dr. H. von Ziemssen; "Psycho-Therapeutics, or Treatment by Hypnotism," by Dr. C. Lloyd Tuckey; "Sexual Activity and the Critical Period in Man and Woman," by Dr. Louis DeSéré.

## NECROLOGY.

### Mr. George Buck.

The Chicago College of Pharmacy announces with regret the death of its President, Mr. George Buck, of the firm of Buck & Raynor.

Mr. Buck was born in Rochester, England, in 1827, and previous to coming to the United States had received a thorough training in pharmacy. Arriving in New York in the summer of 1855 he was engaged for J. H. Reid & Co., then the leading retail firm in Chicago. He remained with this firm as prescription clerk until 1859, when, with Mr. Raynor, also an employé of J. H. Reid & Co., he started in business near the corner of Clark and Washington streets, then a residence neighborhood. The early success and continued prosperity of the firm were due largely to the admitted competency and integrity of its members.

Mr. Buck was an early and consistent advocate of thorough pharmaceutical education, being one of the charter members of this college and having from the first taken a prominent part in its management. He was also prominent in the movement to secure for Illinois the enactment of a pharmacy law, his efforts in that direction dating from 1870, ten years before a law was finally secured.

He was the first president of the State Board of Pharmacy, and had been president of this college continuously since 1886.

He was widely known and universally respected, both by the profession and the people, as a man of high moral worth and sterling integrity, and his death is universally regretted.

Chicago, October 7, 1889.

### Dr. James W. Kerr.

DR. JAMES W. KERR died at his residence in York, Pa., on Monday June 10, 1889, in the 76th year of his age. He was born in Lancaster County, Pa., and graduated in medicine at the University of Pennsylvania in 1840. He was an Assistant Surgeon in the late war, and a member of the American Medical Association since 1848.

J. S. M.

### Dr. Alexander R. Blair.

DR. ALEXANDER R. BLAIR died at his residence in York, Pa., on Thursday, July 16, 1889, in the 63d year of his age. He was born in Lancaster County, Pa., and received his degree of M.D. from the Jefferson Medical College, Philadelphia, in 1853. Dr. Kerr and Dr. Blair were the organizers of the York County Medical Society and members of it at their death. They were members of the State Medical Society. Dr. Blair joined the American Medical Association in 1858. He also served as Assistant Surgeon during the late war.

J. S. M.

## MISCELLANY.

**PARIS EXHIBITION.**—Wm. R. Warner & Co., the well-known manufacturing pharmacists of Philadelphia, were awarded a silver medal at the Paris World's Fair in recognition of the excellence of their pills and effervescent salts. This is the thirteenth World's Fair medal that Warner & Co. have received.

**HEALTH IN MICHIGAN.**—For the month of October, 1889, compared with the preceding month, the reports indicate that scarlet fever, puerperal fever, influenza, pneumonia, diphtheria, pleuritis and typhoid fever increased, and that cholera infantum, cholera morbus, dysentery, cerebro-spinal meningitis, diarrhoea and measles decreased in prevalence.

Compared with the preceding month, the temperature in the month of October, 1889, was much lower, the absolute humidity was considerably less, the relative humidity was slightly less, the day ozone and the night ozone were less.

Compared with the average for the month of October in the three years, 1886-88, inflammation of brain, diarrhoea, typhoid fever, pneumonia and puerperal fever were more prevalent, and cerebro-spinal meningitis, cholera infantum, membranous croup, diphtheria, erysipelas and measles were less prevalent in October, 1889.

For the month of October 1889, compared with the average of corresponding month in the three years 1886-88, the temperature was lower, the absolute humidity, the relative humidity, and the day and night ozone were less.

Including reports by regular observers and others, diphtheria was reported present in Michigan in the month of October, 1889, at 63 places, scarlet fever at 54 places, typhoid fever at 113 places, and measles at 15 places.

Reports from all sources show diphtheria reported at 29 places more, scarlet fever at 34 places more, typhoid fever at 66 places more, and measles at 8 places more, in the month of October, 1889, than in the preceding month.

## *Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from November 9, 1889, to November 15, 1889.*

Capt. C. N. B. Macauley, Asst. Surgeon, is granted leave of absence for one month, to take effect about the 29th inst. Par. 2, S. O. 166, Dept. of the Missouri, Ft. Leavenworth, Kan., November 8, 1889.

The following changes in the stations of medical officers serving in this Department are hereby made, viz.:

Capt. L. W. Crampton, Asst. Surgeon, from Ft. Lyon, Col., to Ft. Sheridan, Ill.

Capt. W. H. Corbusier, Asst. Surgeon, from Ft. Hays, Kan., to Ft. Lewis, Col.

First Lieut. F. J. Ives, Asst. Surgeon, from Ft. Lyon, Col., to Ft. Sill, I. T. Par. 3, S. O. 167, Hdqrs. Dept. of the Missouri, Ft. Leavenworth, Kan., November 9, 1889.

By direction of the Secretary of War, Capt. Louis M. Maus, Asst. Surgeon, having relinquished the leave of absence on surgeon's certificate of disability granted him in S. O. 249, October 25, 1889, from this office, will, upon being relieved from duty at Ft. Porter, N. Y., as directed in S. O. 242, October 17, 1889, from this office, proceed without delay to Ft. Stanton, N. M., and report in person to the commanding officer, Dept. of Arizona. Par. 8, S. O. 261, A. G. O., Hdqrs. of the Army, Washington, November 8, 1889.

By direction of the Secretary of War, the following assignments of officers of the Medical Department (recently appointed) are ordered:

First Lieut. Charles Willcox, Asst. Surgeon, will report to the commanding officer at Ft. Columbus, N. Y., for duty at that station.

First Lieut. Harlan E. McVay, Asst. Surgeon, now at Ft. Mackinac, Mich., will report in person to commanding officer of that post for duty.

First Lieut. Euclid B. Frick, Asst. Surgeon, will proceed from Philadelphia, Pa., to Ft. Keogh, Mont., for duty at that station.

## *Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine-Hospital Service, for the Three Weeks Ending November 9, 1889.*

Surgeon George Purviance, granted leave of absence for twenty-one days. November 8, 1889.

Surgeon H. W. Austin, to inspect unserviceable property at St. Louis Marine-Hospital. November 4, 1889.

Surgeon J. M. Gassaway, relieved from duty at New Orleans, La.; to rejoin station at Cairo, Ill. October 23, 1889.

P. A. Surgeon C. E. Banks, granted leave of absence for thirty days. October 28, 1889.

Asst. Surgeon J. B. Stoner, ordered to Vineyard Haven, Mass., for temporary duty. November 6, 1889.

Asst. Surgeon A. W. Condict, ordered to Cairo, Ill., for temporary duty. November 4, 1889.

Asst. Surgeon G. M. Guiteras, ordered to Washington, D. C., for temporary duty. November 8, 1889.

Asst. Surgeon J. F. Groenevelt, ordered to New York, N. Y., for temporary duty. November 5, 1889.

## ADDRESSES.

### THE AMERICAN ACADEMY OF MEDICINE;

ITS OBJECTS; ITS SIGNS OF PROMISE AND ITS  
OBSTACLES; ITS FIELD OF WORK; AND  
SOME SUGGESTIONS LOOKING TO AN  
INCREASE OF ITS EFFICIENCY.

*Address of the President delivered at the Annual Meeting in Chicago,  
Ills., Nov. 13, 1889.*

BY LEARTUS CONNOR, A.M., M.D.,  
OF DETROIT, MICH.

*Fellows of the American Academy of Medicine:*  
—By one of those strange freaks that make the action of otherwise clear headed people unaccountable, you last year elected me to the office of your chief servant. As I was unavoidably absent from the session during which this action was taken, I did not learn of it until many hours after you had adjourned. Hence, nothing was left me other than to endeavor to understand and execute your wishes. Respecting the outcome of my service you are all in position to judge. The new plans of operation, proposed by Dr. Gerrish last year and adopted by the Academy, called for the appointment of several new committees, whose reports speak for the wisdom of the changes and the faithful service of these committees. In general it seems to me that the changes, and the individuals, who at much personal sacrifice have rendered them so successful, deserve the full approval of the Academy.

For the first time in its history the Academy holds a meeting in the West. For the first time, it comes into personal contact with the mighty material forces clustering about the great lakes, the vast rivers of the American Continent, the boundless prairies, and the pure breezes that starting far up in the heavens by the tops of the Rockies, sweep for thousands of miles over fertile plains. For the first time, it gazes upon the marvellous civilization that has sprung, like Aladdin's lamp, in the vast garden that is bounded by the great lakes, the Gulf of Mexico, the Alleghanies and the Rocky Mountains. Within this area, is being developed a civilization having the largest and most favorable conditions for gigantic growth, untainted by the dis-

turbing influences of Europe or Asia, as the obstruction of vast mountain chains separate it from ready access to the great ferries which ply the Atlantic and Pacific. Here, if anywhere, will appear the typical American. Here, if anywhere, will be seen the greatest differentiation from all other peoples and races on the earth, and the most perfect blending of all types under the influence of the governing Anglo-Saxon direction. Here, if anywhere, will be seen the product of the richest soil, the most varied climate, the most perfect air, the purest water, the grandest forests, and the most majestic rivers. Here men and women do and dare all things in their efforts to bring under subjection, the countless natural riches everywhere found in such profusion. Into this atmosphere, most typically represented in this its largest city, the American Academy of Medicine for the first time comes. That it will grasp some idea of the medical needs of this superb region, and be able to initiate such schemes as will result in their early supply, is assured. That the Fellows will better appreciate the problems before them, see additional grounds for encouragement, and appreciate more definitely the obstacles to be met and overcome, is our hope. Within this vast area is a teeming population, the parent of millions who within a short time will occupy these fat places. The medical profession throughout it are in a plastic state of development. Now, better, than ever after it can receive and execute lessons of its matchless opportunities, and the measures requisite for their best improvement.

Some have said that the American Academy of Medicine is founded upon a new idea, a "fad" born of an aristocratic modern notion. As a fact, we find that Hippocrates standing at the dawn of historic medicine, urged earnestly that "the preliminary training of medical men be made as broad and as deep as possible." Farther, by precept and example the same idea has been maintained by all the famous medical men from Hippocrates to Alonzo Clark, as was abundantly shown in the eloquent and scholarly address of Dr. George Jackson Fisher, last year. We, the lineal descendants of the worthies, are simply endeavoring to maintain the faith once delivered to the "fathers," thousands of years ago. Our

mission is to galvanize into life, the truth of the importance and value of a preliminary education, that has become obscured by the overshadowing influence of commercialism. We strive to aid in the establishment of such conditions as will ensure the possession by every medical man of such general knowledge of literature, science, art and trade in their broadest as well as narrowest relations, so that he may rank as a real teacher, companion and friend of the cultured and the uncultured. We rejoice that the medical profession contains large numbers of such men, but the Academy would have them universal, the rule not the exception. The change which the attainment of this end *would make*, is illustrated by the change which occurred in the classes of the Harvard Medical School during the interval from 1870 to 1880. On the former date it will be remembered that this school raised its standard of preliminary requirement, and proportionately its general curriculum. In brief it began to teach modern medicine in a rational manner. President Elliot in describing this change says: Until 1870 the students in the medical class of Harvard were noticeably inferior in bearing, in manners, and in discipline to the students in other departments; now they are indistinguishable from other students." He adds, "a corresponding change in the medical profession at large would be effected in twenty years if all the medical schools of the country would institute a reasonable examination for admission. Under the present order of things, the American Physician and Surgeon may be, and often is, a coarse uncultivated person, devoid of intellectual interests outside of his own calling, and quite unable to speak or write his mother tongue with clearness and accuracy." To set into operation agencies which will enable all medical students to rank with any other professional students in gentlemanly bearing, and supplant the coarse ill bred, ignorant physician by one who can comprehend the intellectual forces operating in the community about him, and who can meet on equal terms any individual who has become possessed with the intellectual training of his time, such is the mission of the Academy.

Then, if ever such a time comes, will the degree of doctor of medicine be an introduction and passport to any and every class in any community. Then, medical men will take rank among the leaders in all things pertaining to the best interests of the communities in which they live. Until then the physician's diploma avails for naught except as a license to practice medicine, in some States. Its general worthlessness becomes more and more apparent as State after State refuses to accept it because of the lack of uniformity of the knowledge which its possessor may have acquired. Until a change is brought about such as the Academy seeks, each doctor

must introduce himself, pass his individual examination before the guardian Board of the State in which he desires to live, and before the cultured people in the community among whom he casts his lot. Having passed these examinations successfully, he occupies a place in the community such as his personal merit has won just as does the blacksmith or farmer. The *London Lancet* stated the case as follows: "If medicine is to acquire and sustain a high respect for its membership, such as is given men of science, art and other professional callings, its membership must be equipped with all the richer learning which is required to hold its own in a world that is daily becoming more cultured, and will certainly demand more of its medical advisers. Its members must have large physical and mental energy, capacity for long continued efforts, an unselfish devotion to their work, and a high moral life. The practitioner of the future must know more than his father knew, and know it in a different manner. Here and there one may leap over all obstacles, and in spite of unfortunate antecedents mount to the front rank. But the vast majority of the medical profession can reach that rank only by the most thorough and systematic cultivation of every physical, mental and moral faculty before they enter upon the study of medicine. Then if ever the physician must make the acquaintance of the great world of literature, philosophy, art, poetry, language, etc., which has been growing out of the labors of countless hosts who have lived, and by their toils made it possible for us to accomplish more than they in the short span of human life. At such time or never the student must master the objects and forces, beneath the earth's surface, upon the earth's surface, and above the earth's surface. By microscope and telescope, and all other scopes, by retort and test tube, by heat, light, electricity, chemical force and gravitation, he must follow the great teachers into the revealed mysteries of nature. Only thus can he come to know something of himself, and of the human beings whose ills he would learn to prevent, remove or alleviate. Only by such training can he hope for a manly development, which will rank him with the best educated men of the world." To increase the number of those who shall thus stand as the representatives of medical science and art, is the crowning glory of the Academy's labors.

But the objection is made such development will not pay; it costs too much time, too much money, for the return in fees. To this I reply that the history of medical men shows clearly:

1. Those, who enter upon the study and practice of medicine for the fees they hope to receive, have made a fatal mistake. They had better, at once, devote their time and energies to some calling in which it was possible to accumulate large

fortunes. The pure tradesmen has no place in the temple of medicine more than he has in the temple of religion. He may don the horse's skin to cover his own, but the donkey's ears will stick out and betray him. He may be sure that at some time the Master will enter and drive from the Temple "the money changers and those who sell doves."

2. The highest honors, the largest fees, the most enduring renown, the greatest glory, have, during all historic time come to such physicians as have, first and last, sought the uplifting of the profession to which they belonged. In the language of the Great teacher "those who have sought the Kingdom of God, have also had added to them all other earthly things." In brief it is certain that medical men developed and equipped as we have desired, would reap the very highest fees, the most distinguished honors that earth can give. We trust that this Academy may in the near future make plain to the world that its principles once fully enforced by the profession, would be attended by a vast increase of the solid cash.

It is fitting, from time to time, to look over the field in which we labor and note the progress made in its cultivation, and the signs of promise for the future. Of these I note a few for our encouragement. In truth it must be said, that the Academy is but one of numerous agencies, all striving toward the accomplishment of the same end, by diverse routes. All of these we cordially welcome, and wisely seek to increase in efficiency and to multiply.

1. It will be remembered that last year the College of Physicians and Surgeons of New York, placed in active operation a preliminary examination of considerable severity. The result shows that its classes maintained a size entirely unexpected, though gratifying to the friends of an increased preliminary education. In some other medical colleges the increase of preliminary requirement was attended by equally satisfactory results.

2. Better than this because of larger scope and indicative of a wider interest in preliminary education, is the action of the last New York State Legislature in enacting the following:

"Before the regents of the State of New York, or the trustees of any medical school or college within this State, shall confer the degree of doctor of medicine upon any person who has not received the baccalaureate degree in course from a college or university duly authorized to confer the same, they shall require him to file with the secretary or recording officer of their university or college, a certificate showing that prior to entering upon the study of medicine, he passed an examination conducted under the authority, and in accordance with the rules of, the regents of the University of the State of New York, in

arithmetic, grammar, geography, orthography, American History, English Composition, and the Elements of Natural Philosophy, and such certificate shall be signed by the secretary of the regents and countersigned by the Principal or Commissioner conducting the examination."

This enactment shows that the principle for which the Academy contends has been adopted by the State of New York. The examination is low, and the enactment imperfect in some details, but as a whole it is a great step in advance. We can rely upon the spirit which prompted, and the intelligence which formulated *the enactment* to eliminate imperfections, and advance the requirements as public sentiment shall desire.

3. It is meet that the Academy should take heart, because the enemies of the Illinois State Board of Health failed to accomplish its ruin this year. Its position, that no diploma will be recognized as entitling its possessor to practice medicine in Illinois unless given by a medical college which requires a definite preliminary examination, still remains the law of this State, and is enforced. The service of this board in teaching the doctrine of the absolute necessity of some preliminary requirement of medical students before entering upon college training, has been of incalculable value. It is doubtful whether any moral suasion would have been so effective, with the medical colleges, the medical profession, and the laity and other State Boards of medical examiners. As the pioneer of teaching this doctrine by law it will ever retain the gratitude of such as are able to appreciate its difficulties. Profiting by its success and failure, other boards have been established upon a higher plane, but all cheerfully acknowledge their debt of gratitude to this board.

4. The results exhibited by the Minnesota State Board of Medical Examiners, under the last phase of its development, are especially encouraging. Under the old Act, Minnesota licensed in 1885 one hundred and forty-six physicians. During the following two years the State rapidly increased in population, and yet under the last Act only one hundred and forty per year were licensed during the two following years. At the examination held October, 1889, of seventeen applicants only twelve were licensed. From this statement we are prepared to hear that Minnesota has but one physician to thirteen hundred people, while in the rest of the States it is affirmed that one physician exists to every five or six hundred people.

The last Act, in brief, requires all persons, desiring to begin the practice of medicine in Minnesota, to pass a scientifically practical examination by a Board independent of all medical schools. No candidate is admitted to examination unless he presents a diploma from a medical school that requires a preliminary examination upon the fol-

lowing branches: English grammar, composition, geography, algebra, physics and natural sciences, together with one of the following languages: Latin, French or German. In addition, the college must require attendance upon at least three full courses of instruction of not less than six months duration, before conferring the degree of doctor of medicine. The practical result of this law has been to restrict the number of new men who have entered upon the practice of medicine in Minnesota, and very greatly elevate the general and special training of the new members. It has also given a stimulus to medical colleges in their efforts to advance the standard of preliminary requirement. It must be that in the near future the profession of Minnesota will possess a higher grade of general culture and professional acquirement than in the past, or than is possessed by other States. As this accords with the aims of the Academy, it can rejoice in such tangible proof of progress.

5. In Montana, Virginia, North Carolina, etc., there are also laws bearing upon the increase of the preliminary requirements of medical students. While these are less radical than the Minnesota Acts, they contain the seed which is sure to grow until they have equalled if not surpassed the foremost.

6. At the late meeting of the American Medical Association Dr. Millard, so long actively engaged in the reformatory work in Minnesota, presented a scheme urging the adoption of such measures as would result in the adoption, by each State, of the Minnesota Acts. His idea was regarded with favor by those present. That difficulties attend its speedy realization does not render it less appropriate that we should accept it as an indication of the development of our cherished principles. We are ready to grant that law cannot accomplish all the reform we seek, still we must admit that law can do much in numerous directions otherwise unattainable. It can lay its heavy hand upon the wilful transgressor, and make him respect the forms of propriety. The discussion of such laws incident to their formulation in each State, to their passage through the legislatures and to their enforcement, compel attention from millions of the laity, and thousands of the profession, who otherwise would not give the matter a moment's thought. Medical colleges would thus learn that they cannot with impunity, for trade, prostitute the profession to which they belong. The law can make it profitable for the colleges to adequately increase their preliminary and other requirements.

7. The pharmacists, at their last annual meeting, bewailed the low condition of the general culture of their craft, and endeavored to formulate some plan by which such culture could be increased. They sought to have the professional side of their calling occupy a more prominent

share of attention. The preliminary requirement suggested as fitting for those who desired to enter upon the study of pharmacy compares favorably with that of most medical colleges, which enforce any preliminary examination. Thus in many directions the spirit of reform is abroad. While it works slowly, it is surely coming to the front.

(To be concluded.)

## ORIGINAL ARTICLES.

### THE POSSIBLE DANGER OF INJURY TO THE MIDDLE EAR CAVITY BY THE USE OF NASAL ATOMIZATION, ILLUSTRATED BY THREE CASES.

*Read in the Section of Laryngology and Otology at the Fortieth Annual Meeting of the American Medical Association, held at Newport, June, 1889.*

BY C. W. RICHARDSON, M.D.,  
OF WASHINGTON, D. C.

In calling attention to the few facts which I am about to lay before you, I am aware of my trespassing upon what might be called sacred territory and, therefore, do not come before you with ill-advised and hastily drawn conclusions. I know I shall meet with considerable skepticism, for such is usually the lot of those who lay bare possible injurious effects of previously considered harmless therapeutic agents, especially after they have become the cherished idol of the whole profession. I can but think that the skeptics will be vastly in the minority when I have summed up the result of my labor. I shall first give you several illustrative cases, followed by several experiments and conclusions. The object of this paper is to call your attention to the possible danger of injury to the middle ear as a result of nasal atomization, especially if such pressure is direct, as in the Davidson and Snowden atomizing tubes. Two of these cases developed in my own practice during the last year. Latterly I have been more guarded in the use of sprays and the amount of pressure used, and, on this account, have not had the misfortune to meet with any further mishaps.

*Case 1.*—That of a woman 27 years of age; married. Came to me during the month of December on account of a post-nasal catarrh attended with the secretion of an excessive amount of mucus. On the 10th of January I admitted her to my consultation room, immediately after dismissing a patient having an atrophic rhinitis, on whom I had been using a spray of high pressure to remove the adherent mucus from the nasal cavities. I began the treatment on this day, as usual, by the spraying of the nasal passages with a modified Dobell's solution. I forgot the high pressure, and as I began to spray the left nasal

cavity she involuntarily drew back, made an attempt at respiration, immediately followed by an explosive cough. I quickly cut off the spray. Quickly recovering her power of speech she remarked that she experienced a sensation as though the sprayed fluid had entered directly into her left ear. I assured her that it was impossible for any of the fluid to have entered the ear, and after pursuing the treatment in a more cautious manner dismissed her. About 11 o'clock of the same evening I was somewhat surprised at receiving a summons to call at her house at once. I was informed that her ear had given considerable annoyance since leaving my office. Her pain was great and radiated over side of head and along course of Eustachian tube; remitted almost entirely during next day, and on the third disappeared. Effusion rapidly set in and was attended with considerable deafness, roaring in the ears and resonance of voice. The appearance of membranes I did not note, but remember them as being those of a typical case of otitis media acuta.

*Case 2.*—This case occurred in a gentleman, single, 45 years of age. This patient consulted me during the winter on account of a great hoarseness from which he had suffered since contracting a cold several weeks before. On examining his larynx I found a marked paralysis of the thyro-arytenoidei interni and considerable congestion of the vocal cords. On investigating further I discovered quite a severe pharyngitis and naso-pharyngitis, while in the right nasal cavity there existed a spur, cartilaginous, completely blocking that cavity. His voice was restored and the pharyngeal trouble improved as much as could be expected with the nasal deformity still existing. In March he returned and requested that I should remove the septal spur. I operated on the 2d of March, using cautery knife, with the happiest result—perfect and all sufficient nasal respiration through the right cavity. Everything progressed favorably until the 14th; the septal wound had almost completely healed, and nowhere was there evidence of any inflammatory trouble. On this day I used a little greater pressure in air compressor, in order to remove the small crusts that had formed around the edges of the septal wound. While using the spray the patient remarked, "Why, doctor, that certainly entered my ear." Being quite positive that my patient had not erred in judgment I abstained from further treatment. Before dismissing him I made a post-nasal examination and found this cavity in quite a normal condition—no evidences of any acute inflammatory trouble. I expected trouble, and was not disappointed. On the morning of the 15th the patient called at my office, his facial expression giving unmistakable evidence of a night spent in great suffering. He stated that at about 12 o'clock of the previous evening he was awakened by a severe pain in his

right ear, which increased so in its intensity as to be almost unbearable. He described the pain as of a throbbing character, being intensified by clearing of the throat, coughing and deglutition. Tenderness was manifested by pressure in the angle between mastoid and ramus of lower jaw, but there was complete absence of spontaneous pain over the mastoid region, nor could any be elicited by pressure. No objective noises. Examination of hearing: Tuning fork showed that bone conduction was better upon affected side. Pöhlitz's Hörmesser, R.  $\frac{20}{45}$ , L.  $\frac{15}{45}$ . Inspection of auditory canal: R. E. canal filled with a mass of cerumen; L. E. showed same condition as on right side, but not so great. Cerumen was readily removed by very gentle syringing, a very mild degree of force and the use of only a small amount of water being sufficient to float out the masses. After removal of cerumen the hearing distance was as follows: R. E.  $\frac{30}{45}$ , L. E.  $\frac{25}{45}$ . The membrane of the right ear now being subjected to examination presented the following evidences of a marked inflammation: The central portion of the membrane, that corresponding to the position of the manubrium, presented the condition of intense injection. The processus brevis and the manubrium were completely obscured by an intense swelling and injection of the membrane, which had the appearance of an inverted cone, the apex corresponding to the umbo, and the base to the area of the foramen of Rivini. The anterior, inferior and posterior segments were almost free from any inflammatory evidence. Without further remark one will readily see that our patient had a well developed and intense inflammation of the middle ear cavity. He responded poorly to treatment, but eventually, after considerable suffering, made a perfect recovery.

*Case 3.*—Dr. L., consulted me on the 19th of February of this year on account of a severe pain in the right ear. He was constantly annoyed by more or less obstruction to free nasal respiration. On the previous evening the nasal obstruction had given him considerable inconvenience, and in order to relieve the uncomfortable sensation he resorted to the use of an astringent spray. The spraying fluid consisted of a 5-grain solution of tannic acid. A few hours after this treatment he developed a severe pain in his right ear. On examination I found well-marked evidences of an acute inflammation of the middle ear cavity, which rapidly responded to treatment.

In this connection, and as directly bearing upon this subject, I will here offer three or four cases reported by Dr. Ring in the *N. Y. Medical Record* of August 11, 1888. These cases appeared under the title, "Four Cases of Acute Inflammation of the Middle Ear from the Use of Roosa's Bulb Nasal Inhaler." Dr. H. P. Allen, of Columbus, ably criticised the deductions made by Ring, and showed that he had erred in supposing

the otitis media to be due to the inoffensive bulbs of Roosa. As I wish to show the relationship these cases have to the subject in hand I will give a short synopsis of the treatment adopted previous to the invasion of the otitis media. In Dr. Ring's first case he used a spray of Dobell's, iron and glycerine to the posterior wall of the pharynx, and afterwards inflated, using Pölitzer's bag with Roosa's attachment. In case 2 he sprayed nasal cavities and inflated, as before. In case 3 he sprayed nose, pharynx and throat with Dobell's, and then inflated as in cases 1 and 2. In all three of these cases we have the use of the spray, followed by the inflation of the middle ear by Pölitzer's method. We here report six cases of acute inflammation of the middle ear seemingly due to the use of the nasal spray. It remains for us not only to subject them to careful analysis, but also to ascertain, by direct experimentation, whether a spray under usual pressure is capable of entering the middle ear. It will be necessary, first, to consider the reflex muscular movement excited in the naso-pharynx by the impact of spray; and the minimum of pressure necessary to develop in order to inflate the middle ear cavity.

During the act of spraying, the fluid, more or less irritating, impinges against the posterior wall of the pharynx and, as a result of this irritation, excites the following muscular movement, viz: Very frequently the soft palate contracts immediately; again it remains immobile for a few seconds, or shows only a slight degree of contractility, until there is a tendency of the fluid, which has undergone condensation, to flow into the oral portion of the pharynx, when the palati muscles cause a rapid and vigorous contraction of the soft palate, making a complete separation of the nasal from the oral pharynx. It is hardly necessary to mention that the palati muscles not only exert their action upon the soft palate, but also cause a shortening and dilatation of the mouth of the Eustachian tube. These two factors, the separation of the nasal from the oral portion of the pharynx, and the shortening and dilatation of the tube, are essential elements to the entrance of air or fluid through the Eustachian tube into the middle ear cavity. In inflation of the middle ear by Pölitzer's method these two factors are essential when occurring in conjunction with and simultaneous to the compression of an elastic air bag, the nozzle of which is inserted in one nostril while the other is closed, in order to prevent the outward escape of air.

The maximum of pressure one is capable of producing with a Pölitzer air-bag of a capacity of 300 grams is one-half of an atmosphere, equivalent to a pressure of one-half kilogram. Pölitzer states that with a pressure of 0.1 of an atmosphere air is capable of entering the middle ear cavity.<sup>1</sup> We have now the minimum of pressure one is

capable of evolving from a Pölitzer air-bag, and the minimum of pressure by which air can be forced into the middle ear cavity. The amount of pressure one ordinarily uses in order to produce a spray varies from 10 to 25 pounds, according to the exigencies of the case; a spray of 25 pounds I would consider one of high pressure and very rarely to be used. It is to be distinctly understood that I am here referring to the danger attending the use of the direct pressure spray. It would be difficult to prove that there was sufficient pressure remaining, after loss by resistance and in escape from opposite nostril, to equal the minimum of pressure necessary to cause the entrance of air into the middle ear cavity; yet I hope, by the following simple experiment, to prove that such a pressure exists, if not with unobstructed, at least with partly obstructed nasal passage during the maximum of the spraying act.

In order to obtain the momentum of a sprayed fluid as it passed from the mouth of the atomizing tube it was necessary to construct the following simple device: I first selected an ordinary 8-ounce wide-mouth bottle, into which I placed 3 pounds of mercury. This bottle was stoppered with a vulcanized rubber cork, through which I caused two holes to be bored. Through the larger of the openings I passed a barometer tube, its lower extremity coming almost in contact with the floor of the bottle. Through the other opening I passed a hard rubber tube, bent at right angles; this penetrated 2 centimetres within the calibre of the bottle. Applying cork to mouth of bottle, tubes in position, the apparatus was ready for use.

In order to ascertain if there was any loss in momentum in the spray, due to resistance in the conducting medium, and also where this loss occurred, I instituted the following two sets of experiments:

In the first set of experiments I connected the conducting rubber tube of the air compressor directly to the hard rubber tube of my device. After the above connection had been made I introduced a pressure of 1 atmosphere (1 kl.) in my air compressor. It was now my intention to learn whether the existence of 1 atmosphere of pressure in the air compressor was capable of creating sufficient momentum—the momentum producing sufficient pressure—to raise a column of mercury 76 cm. On turning on the stop-cock, all connections having been made, the mercury rapidly rose in the tube to the height of 76 cm., where it remained stationary, showing that there was sufficient momentum to overcome the atmospheric pressure; or, in other words, the pressure at mouth of tube was as great as in air compressor, there being no appreciable loss in momentum.

In my second series of experiments I interposed between the hard rubber tube and the rubber tub-

ing of the air compressor an ordinary Snowden atomizing tube, all other conditions remaining the same. In this experiment the mercury rapidly ascended the barometer to the height of 54 cm. We observe here a considerable loss of momentum, due to the resistance created in the atomizing tube. The loss is equivalent to nearly one-third of an atmosphere. Calculating from this the amount of momentum existing with the use of a pressure of 12½ pounds in the air compressor, the pressure ordinarily used, we find that it is sufficient to raise a column of mercury 44 cm. in height, nearly equivalent to two-thirds of an atmosphere—a pressure greater than one is capable of generating from a Pölitzer air-bag. Other conditions being present, we have here produced more than sufficient pressure to cause an inflation of the middle ear cavity. The other conditions are the separation of the oral from the nasal pharynx, the shortening and dilatation of the Eustachian tube, and sufficient obstruction in the opposite nostril to interfere with the egress of sprayed fluid. It would be impossible to prove by dynamics, even with all these conditions existing, that sufficient pressure was generated within the naso-pharynx to cause the penetration of a sprayed fluid within the middle ear. It is hardly to be conceived that there would be any greater loss of pressure, by resistance in the nasal passages, than takes place in the atomizing tube, leaving us, approximately, a pressure of more than one-third of an atmosphere, more than sufficient, according to Pölitzer, to cause an inflation of the middle ear cavity. I submitted my experiment to Dr. E. T. Fristoe, professor of chemistry and natural philosophy in the Columbian University, and he concurred in my conclusions. Although dynamics cannot be of any further assistance, we can gain from the following experimental cases positive testimony in this connection. At this time, as my dynamical experiments lacked a certain amount of positiveness, not enough to quell the doubts of the skeptic, and while looking about for further means of demonstrating these facts, the happy idea occurred to me of making use of living material.

One does not care to toy with his private patients, but the exigencies of the case were such, and a possibility of harm so remote, that I concluded to make such use of them. This idea seized upon me more forcibly as I saw my way clear, in treating these cases, to resort to a little collateral and at the same time harmless observation of the effects that would be produced by special modes of procedure. The cases that I utilized were two of otitis media suppurativa chronica, attended with complete destruction of the membrana tympani, and in which it was necessary to use the spray in treating a co-existing rhinitis. These patients had patulous Eustachian tubes. It was only necessary to slightly vary my

usual course of treatment in order to carry out the experiment I had in view. Previously I had never sprayed the nasal cavity after inflating. It was now my intention, after inflating and thoroughly drying out the middle ear cavity—a cavity minus the outer wall—to again spray the nasal passages and note if there then existed any moisture. On following out this line of investigation in both of my cases I found not only moisture, but the actual existence of several drops of the sprayed fluid in the anterior inferior portion of the tympanic cavity. Again, I introduced a sufficient quantity of powdered boracic acid after drying out both cavities, to fill out the existing remnant of tympanum. I now used the spray in the nasal cavity, and, on examining the ear, found that the boracic acid had become moist throughout.

These two illustrative cases, one with and one without artificial obstruction of the nasal cavity, in conjunction with the actual physical demonstration of the amount of pressure generated by a spray, show in a most conclusive manner that a sprayed fluid is capable, under certain conditions, of penetrating the middle ear cavity through the medium of the Eustachian tube.

Even admitting, though, that there is not sufficient pressure produced to cause the entrance of air into the middle ear, no one will deny the entrance of the sprayed fluid into the mouth of, and a certain distance within, the dilated cartilaginous portion of the Eustachian tube. Immediately after the spraying of the nasal cavities, and before the sprayed fluid has had sufficient time to undergo condensation, the patient resorts to the clearing of the nostrils, more or less violently. The clearing of the nasal passages is always, unless there is a constriction or obstruction of the Eustachian tube, however produced, attended with inflation of the middle ear cavity. This inflation is sufficient, I claim, to drive any spray or fluid, which may have lodged within the lower portion of the tube, into the middle ear cavity. While the condition just mentioned is capable of producing an acute otitis media—the fact of its not being more frequently produced not militating against this occurrence—yet I do not admit that this was the manner in which it occurred in the cases above illustrated, but simply refer to this in order to call attention to a further danger to be thought of in connection with promiscuous and continued spraying of the nasal and naso-pharyngeal cavities. To me there is no doubt that the sprayed fluid entered, directly through the tube, the middle ear cavity in the cases under consideration, and that the irritation produced by the fluid was the cause of the subsequent otitis media.

On many occasions I have had patients state that they had experienced a sensation, during the spraying, in the ear, which caused them to suppose that the fluid had entered the middle ear

cavity, without producing any deleterious effect; and I do not doubt but that other laryngologists can recall similar experiences. Subjecting the first case to analysis, we cannot see what other cause than that of the spraying can be assigned as the producing agent. The pharynx and the naso-pharynx were devoid of all evidences of an acute inflammation, and remained so throughout the history of the case. There was no treatment excepting the spraying of the throat, and we have the positive statement of the patient that she experienced a sensation as though something had entered the middle ear. In the second case we have a recent operation,—twelve days since—the wound being in a healthy condition, nearly healed, showing no evidences of inflammation, considerably removed and not in the line of continuity. No treatment was resorted to after the patient indicated the possibility of the entrance of the sprayed fluid into the ear. The third case is so simple as not to require analysis. The occasional occurrence of inflammatory changes in the middle ear in connection with operations upon the septum narium has given rise to the thought that possibly, in most of these cases in which otitis media acuta or suppurativa occur as a sequelæ, they might owe their origin to the spraying subsequently resorted to, rather than to the operation. There seems to me no plausible reason why an operation from 2½ to 5 cm. anterior to and on the opposite wall of the nasal cavity from the orifice of the tube should give rise to an inflammation extending into the middle ear cavity.

We call attention to these facts not with the intention of decrying the use of the spray—I can not conceive how we can replace this valuable cleansing and curative agent—but simply to call attention to certain dangers which may attend injudicious use of high pressure or indiscriminate employment of this agent. The douche produces, as all know and as first called attention to by Roosa<sup>2</sup>, otitis media suppurativa; but its usefulness is undoubted, and there are cases in which its application becomes an absolute necessity. St. John Roosa's calling attention to this fact has not driven the douche into oblivion—it has only caused a suspension of its indiscriminate use and limitation to its proper sphere of usefulness. Many other valued agents and methods are at times attended with disastrous results; calling attention to these effects only makes one more cautious in their employment. Such is my sole intention in connection with this paper.

Before closing my paper I wish to call attention to another condition which the continued and indiscriminate use of the spray may not only aid in the production of, but possibly in certain cases be the direct producing agent, *i. e.*, otitis media hypertrophica. To me it would be very interesting to follow a number of cases in which the

spray had had liberal use, in order to ascertain whether there was any subsequent impairment of hearing. I shall follow this line of investigation where possible, and hope, by calling attention to it, that others may be stimulated in the same direction. The manner in which the spray could aid in the production of this condition we can readily see—it does not rest upon an empty hypothesis. The difficulty would rest in separating this cause, should it be so, from others acting simultaneously.

DR. MACKENZIE said he believed that fluid may enter the ear in any method of cleansing the nose, and that the danger does not pertain especially to the spray. He narrated a case of double otitis media resulting from the use of intra-nasal spray. His remarks did not apply to the nasal douche.

DR. WRIGHT indorsed Dr. Mackenzie's remarks with the exception that auto-douching *often* gives rise to otitis media, but spraying rarely, and that he has never seen trouble resulting from the use of the post-nasal douche in the hands of the physician, while it should *never* be given to a patient to use himself.

DR. H. H. CURTIS said that in cases of middle ear complication following the use of the nasal douche he had observed that the trouble was usually brought about by allowing the fluid to enter through a free nostril and flow out through one contracted by a stenosis.

DR. MACKENZIE said that all who had much experience in the treatment of nasal disease had met with accidents such as that described by Dr. Richardson. There is no method by means of which fluids are introduced into the nares by which the liquid may not enter the middle ear. The accidents from sprays were, however, of not sufficient frequency to warrant extraordinary care in the method. He related illustrative cases.

DR. C. W. RICHARDSON: I called attention to these few facts as much for the information of the members present as for the purpose of calling to your consideration a few points which I was obliged to omit from my paper on account of limited time. I wish to refer to the indiscriminate manner in which hand ball sprays are so frequently placed in the hands of the laity, and the possible danger resulting from this evil practice.

FAITH-CURING OF CONTAGIOUS DISEASES SUPPRESSED.—The Board of Health of Matteawan, N. Y., having encountered a case of diphtheria that was being neglected by some faith-curing practitioners, declared an immediate quarantine, which was maintained by the police. A reputable physician was put in charge of the case, and the child began to improve.

## STAMINA.

*Read in the Section of State Medicine, at the Fortieth Annual Meeting of the American Medical Association, June, 1889.*

BY A. N. BELL, A.M., M.D.,

OF BROOKLYN, N. Y.

The object of this essay is to reduce the signification of the words "susceptibility," "predisposition" and "heredity."

In the progress of bacteriological knowledge, there is too little attention paid to the organic conditions of health, and the resisting power of the system in conflict with antagonistic forces. Thirty years ago, while engaged in the study of "Living Things," the writer had occasion to observe: "Man's life is inseparably linked with the plants and animals which coexist with him, and these are the issue of long anticipations and preparations, where all the changes produced in other objects occur according to a relation existing among the substances changed. Latitude, elevation, nature of the soil, degree of cultivation, relative position in regard to mountains, forests, rivers, etc., and general aspect of the neighborhood, all modify the condition of man, and prove his adaptability by such effects as serve to make him understand his relations to what is around him. We cannot prevent the dews of heaven, nor the heat of the sun, nor the progress of decomposition; but we can understand the course and order of natural phenomena, we can trace out the laws that govern them and ascertain our relations to them."<sup>1</sup>

The reward of man's cosmopolitan nature and free agency is the progress of human welfare, even though won at the cost of impaired health and premature death by those who do the most to promote it. But the influence is reciprocal. Man reacts upon nature no less than nature upon him. Indeed, the changes effected in natural phenomena by human agency are the striking characteristics of conditions promotive of, or in conflict with human health everywhere. This reciprocal action should, above all things else, make the progressive man alive to the importance of constructing and sustaining his ability to contend against the antagonistic forces—both natural and artificial—with which his sphere of life is everywhere intimately associated. And in the application of this knowledge he will learn that health is something more than mere freedom from disease. Health is *opposed* to disease and its causes by the relative integrity, strength and vigor of all the organs and functions of the body, fortified by such conditions as the human organism depends upon for its fabrication and resistance. For example: Two individuals, the one endeavoring to live by rule, and having much to say about the "laws of health," afraid to run

upstairs because it makes the heart beat more rapidly, hurries the respiration and fills the lungs; can't eat cheese because it constipates the bowels, nor cherries for the contrary reason; never drinks water, or but very little, with meals; can't take a glass of milk at bedtime, or a hot roll for breakfast, because such food always sets heavy on the stomach; never eats bacon or pork, and eschews fat meat of all kinds; takes an hour at meals and always leaves off hungry; would not take a cold bath for anything; who prefers the weight of a thick furlined overcoat or cloak to a light one and a brisk walk on a cold day; and sundry other postulates promotive of tenderness. And the other—the reverse: Who is neither afraid to hurry at his meals or to his business; not only runs up stairs, but a long hill, or if in a hurry, forty rods or more after a railroad car; who has taught his stomach, as he has his arms, legs, heart and lungs such lessons in gymnastics as not to be too dainty, and to profit by the variation; who satisfies hunger and thirst; when among Romans, live as they do; fuds hog, hominy and hot bread digestible, wholesome and nutritious; has, in short, never tried to live by any rule, except temperance in all things and protection against the extremes of weather. Both of such persons may be equally free from disease, but is it necessary to add that the power of the latter to resist it in every respect—whether it be inhaled, swallowed, inherited, or by exposure to inclement weather—is greatly in favor of the well-nourished and the strong? And the relative immunity depends not upon predisposition, but upon stamina.

With regard to certain infectious diseases to which children are especially liable, in part, doubtless, because of their greater functional activity, but chiefly because their power of resistance has not yet become sufficiently fortified—for it is well known that adults generally who have not encountered those diseases in childhood rarely contract them subsequently—the same relative immunity exists; the strong and vigorous child is much less likely to contract them than the feeble; and the convalescent, those who are particularly feeble from any one of such diseases, are well known to be the most of all liable to attack and to succumb from another. And of pulmonary consumption, the most prevalent and the most fatal of all diseases, who does not know that enfeeblement invites it? That individuals are less and less liable to it—whether traceable to hereditary taint or otherwise—in proportion as coddling has been avoided, appetite for wholesome fat food cultivated, cold bathing habitual, protective but loose clothing worn, and exercise in the open air unrestrained? By the maintenance of these conditions all the processes of healthy organization are promoted and the constitution fortified against tubercle bacilli as in

<sup>1</sup> "Knowledge of Living Things with the Laws of their Existence," by A. N. Bell, A.M., M.D. Bailliere Brothers, New York, 1860.

like manner against other disease germs, no matter whence the quarter or at whatever age of the individual exposed; and no less against diseases not attributable to germs. And the more if we accept Metschnikoff's theory of the office of the *leucocytes* or white blood corpuscles, for these in both number and strength depend upon proper nourishment. "In health," says Kirkes, "the proportion of white to red corpuscles, which, taking an average is about 1 to 500 or 600, varies considerably, even in the course of the same day. The variations appear to depend chiefly on the amount and probably also on the kind of food taken, the number of leucocytes being very considerably increased by a meal, and diminished again on fasting. Also in young persons, during pregnancy, and after great loss of blood, there is a larger proportion of colorless blood corpuscles, which probably shows that they are more rapidly formed under these circumstances. In old age, on the other hand, their proportion is diminished."<sup>2</sup>

No good observer will fail to recognize the coincidence of the condition which diminishes the proportion of leucocytes and the increased liability to disease—that of fasting; or note the no less remarkable coincidence, the diminution in the number of the leucocytes and increasing infirmity of old age. The leucocyte or colorless blood corpuscle is an *amaba*, the simplest type of a living thing; a jelly-like mass of protoplasm, of the same consistence throughout, which possesses the property of moving about and capturing its prey by changing its form by the protrusion of first one part of its body and then another, and of extemporizing a stomach by wrapping itself around any nutritive particle with which it comes in contact and digesting it. On account of this peculiar property and apparent function of the leucocytes Metschnikoff has conferred upon them the name of *phagocytes*—eaters—as expressive of their most distinctive feature, and of the process in general, *phagocytosis*.

"It has long been known," says Dr. William Osler,<sup>3</sup> "that foreign bodies such as ligatures, portions of dead bone and other substances, may be completely removed by leucocytes.

"Nowhere in the body do we have such a facility for studying the action of phagocytes as in the organs of respiration, in which, with the cilia of the bronchial mucosa, they share in the work of cleansing the air-passages; and of these two important agencies it is hard to say which plays the more important part in the expulsion of those particles of foreign matter which, in cities at least, we constantly inhale. There are several groups of cells engaged in this work: The ordinary mucus corpuscles; the alveolar epithelium;

the connective tissue-elements of the pulmonary stroma, and the leucocytes of the lymph tissue in the bronchial, tracheal, mediastinal glands.

"The examination of the morning sputa of a cigarette smoker, or of a person who has been exposed to a dusty atmosphere, shows very clearly that no small proportion of the carbon grains is included within protoplasm. The free granules are abundant, but almost every leucocyte has its little load which it has picked up on its road from the finer tubes to the trachea.

"It is possible to conceive, under certain conditions, of the air cells gradually filling, were it not for the activity of phagocytes, derived largely from the alveolar epithelium, which stands, as it were, at the gateway of the lymphatic circulation.

"In dwellers in the country, as well as in wild animals, breathing an air comparatively pure, the cilia and the phagocytes in the air-passages appear quite able to prevent access of the carbon grains to the lung tissue; whereas in the dwellers in the cities, and in animals kept in confinement, the impurities in the air are so abundant that these agents are insufficient, and sooner or later the grains penetrate the air cells.

"The steps in this process described may be followed in the lungs of any town dweller, but to see in perfection the remarkable activity of the pulmonary phagocytes, one must study the early stages of anthracosis, particularly in those exceptional cases which we see occasionally when a miner has been killed by accident or dies of acute disease. It is not, I think, too much to say that the larger part of the pigment contained in lungs, almost, if not quite, black, is enclosed in protoplasmic cells.

"A physiological process in which phagocytes play a leading rôle, is the removal and disintegration of the red blood corpuscles which have lived their life and are no longer fit for work. The cells containing the red blood-corpuscles, which are found in the bone marrow and in the spleen, however much opinion may differ as to their mode of origin, cannot, I think, be regarded in any other light than as phagocytic elements with this definite function.

"In the mature body we have seen that in the lungs, in the intestines, and in the blood-making organs, the phagocytes have most essential functions; but the question of chief interest to-day relates, not so much to this normal process about which there has never been much doubt, as to the supposed part which these cells take in protecting the body against the invasion of parasites.

"Metschnikoff has studied a number of diseases, erysipelas, anthrax, relapsing fever, and tuberculosis, with a view of finding facts in support of this theory, and his communications within the past four years have been numerous and elaborate.<sup>4</sup>

<sup>2</sup> Kirke's Hand Book of Physiology, vol. 1, page 79.

<sup>3</sup> Address before the Alumni Association of Bellevue Hospital, New York, April 3, 1889.

<sup>4</sup>Published chiefly in Virchow's Archiv.

"In erysipelas the cocci are attacked first by the leucocytes filling the lymph spaces, which rapidly proliferate and actively eat the micro-organisms. Not alone do the colorless corpuscles act as phagocytes, but the fixed connective tissue cells assist in an important manner. In cases of recovery he found that behind the advancing cocci the leucocytes were crowded with parasites, which showed evidences of digestion and destruction. The connective tissue cells do not appear to attack the cocci, but are chiefly concerned with the absorption of the inflammatory exudate, even taking up the leucocytes which have died. In fatal cases there was enormous development of micrococci, the majority of which lay free in the tissues not enclosed in the phagocytes.

"As we might suppose, the views of Metschnikoff have met with sharp criticism in many quarters, and from no one more ably and at greater length than from Baumgarten.<sup>5</sup> While not denying that the leucocytes eat the bacteria, he claims that the process is by no means universal, and is carried on so unequally, that we can scarcely speak of an active warfare waged against the parasites.

"Metschnikoff states that in malaria the parasites are attacked chiefly in the spleen and the liver by the larger phagocytes existing in these organs, and to a much less extent by the leucocytes in the circulating blood.

"We see then, in malaria very little evidence in the blood favoring a theory of phagocytosis; certainly no such campaigning on the part of the leucocytes as might be expected from the presence, in such numbers, of foes so destructive to the red corpuscles."

Dr. Osler concludes that: "While phagocytosis is a wide-spread and important physiological process throughout the animal kingdom, and while it undoubtedly plays a most important part in many pathological conditions, the question of an active destructive warfare waged by the body cells against the microorganisms of disease must still be considered an open one." (*Medical News*.)

Whatever may be the final verdict with regard to the antagonism of the phagocytes to disease germs generally, it appears to be clear that their proportion and their energy are in direct relation with the vigor of the organism, and dependent upon the same sustaining conditions.

Sir Wm. R. Grove, F.R.S., the distinguished author of "Antagonism," (the subject of a lecture delivered at the Royal Institution of Great Britain, April 20, 1888,) after alluding to Prof. Metschnikoff's theory, says:

"Let us now consider the external life of animals. I will take as an instance, for a reason which you will soon see, the life of a wild rabbit. It is throughout its life, except when asleep (of

which more presently), using exertion, cropping grass, at war with vegetables, etc. If it gets a luxurious pasture it dies of repletion. If it gets too little it dies of inanition. To keep itself healthy it must exert itself for its food: this, and perhaps the avoiding its enemies, gives it exercise and care, brings all its organs into use, and thus it acquires its most perfect form of life. I have witnessed this effect myself, and that is the reason why I choose the rabbit as an example. An estate in Somersetshire, which I once took temporarily, was on the slope of the Mendips Hills. The rabbits on one part of it, viz., that on the hillside, were in perfect condition, not too fat nor too thin, sleek, active and vigorous, and yielding to their antagonists, myself and family, excellent food. Those in the valley, where the pasturage was rich and luxuriant, were all diseased, most of them unfit for human food, and many lying dead on the fields. They had not to struggle for life, their short life was miserable, and their death early: they wanted the sweet uses of adversity—that is, of antagonism.

"The same story may be told of other animals. Carnivora, beasts or birds of prey, live on weaker animals; weaker animals herd together to resist, or, by better chance of warning, to escape beasts of prey: while they, the herbivora, in their turn are destroying vegetable organisms.

"I now come to the most delicate part of my subject, viz., man (I include women of course). Is man exempt from this continual struggle?

"It is needless to say that war is antagonism. Is not peace so also, though in a different form? It is a commonplace remark to say that the idle man is worn out by ennui, *i. e.*, by internal antagonism. Kingsley's "Do-as-you-like" race—who were fed by a substance dropping from trees, who did no work, and who gradually degenerated until they became inferior to apes, and ultimately died out from having nothing to do, nothing to struggle with—is a caricature illustrative of the matter.

"As, with food or exercise, deficiency is as injurious in one as is excess in another direction, so, as affecting the mind of communities, as I have stated it to be with individuals, the effect of a life of ease and too much repose is as much to be avoided as a life of unremitting toil. The Pitcairn Islanders, who managed in some way to adapt their wants to their supply, and to avoid undue increase of population, are said never to have reached old age. In consequence of the uneventful, unexcited lives they led, they died of inaction, not from deficiency of food or shelter, but of excitement. They should have migrated to England! They died as hares do when their ears are stuffed with cotton, *i. e.*, from want of anxiety. We have hope in our suffering, and in the mid-gush of our pleasures something bitter surges up."

<sup>5</sup> Loc. cit.

"We look before and after,  
And pine for what is not ;  
Our sincerest laughter  
With some pain is fraught ;  
Our sweetest songs are those which tell of  
Saddest thought."

(*Nature.*)

With reference to heredity especially (as too commonly understood), in the face of what has been brought forward, while it has undoubted significance with reference to certain constitutional diseases, it is, notwithstanding, amenable to the same organic forces as feebleness of constitution in general ; dependent more upon parental feebleness and unhealthful regimen in early life than upon specific tendency. The offspring of poorly nourished, dyspeptic parents, for illustration, are scarcely less liable to pulmonary consumption than the offspring of those affected with that disease ; and the offspring of drunkards and of those who use narcotics to excess are well known to be fully as liable to insanity, epilepsy and idiocy as they are to inebriety. Indeed, hereditary feebleness of constitution is the prevailing "predisposition" to disease, and this, associated as it frequently is with inadequate nourishment and neglectful regimen during childhood, accounts in a great degree for the excessive mortality which obtains in infancy.

But in advocating more attention to personal regimen as the chief means of cultivating constitutional stamina and thus increasing the power of resistance to disease, which it is the purpose of this paper to urge, there should be no diversion from the effort to destroy the foci of disease germs and to maintain healthful surroundings. It should always be borne in mind, however, that the ability of the practical sanitarian to successfully cope with infectious disease-germs and their foci, and to maintain his own immunity, is the same as that of other persons : in proportion to the power of resistance, based upon constitutional and cherished stamina.

### WHEN SHOULD THE OBSTETRIC FORCEPS BE USED? AND WHAT FORM OF INSTRUMENT IS REQUIRED?

*Read in the Section of Obstetrics and Gynecology at the Fortieth Annual Meeting of the American Medical Association, held at Newport, R. I., June, 1889.*

BY WILLIAM S. STEWART, A.M., M.D.,

PROFESSOR OF OBSTETRICS AND CLINICAL GYNECOLOGY IN THE MEDICO-SURGICAL COLLEGE PHILADELPHIA, PA.

The question as to when the obstetric forceps should be used follows on the assumption that there are times when they are required. Taking for granted this necessity let us briefly refer to it, enumerating in the first place the circumstances and conditions which do *not* justify the application of the blades.

The forceps should never be used simply to

gratify nervous patients, interfering nurses or meddlesome women, nor to save the time of a practitioner, busy or otherwise. The possibility and comparative ease of applying the blades within the partially dilated os is no indication that even the most careful use in such cases may not result in the rupturing of the cervix and other soft parts, exposing the patient to the immediate dangers from hæmorrhage, septicæmia and the various inflammatory conditions, and as well the possibility of life-long suffering.

The indications for the use of the obstetric forceps may be enumerated as follows :

1. Where speedy delivery is necessary in the interest of either mother or child ; as in eclampsia, hæmorrhage, exhaustion, prolapse of the cord, etc.
2. Where the ordinary forces of labor are insufficient to overcome the obstacles to delivery ; as in narrowing or partial obstruction of the birth-canal within certain limits, uterine inertia, large foetal head, malpositions, and where the head is engaged in the pelvis and there has been no advance for some time, the "rebound" during the interval between the diminishing pains having ceased.

In addition it is of importance in all cases before applying the forceps to be assured of the existence of the following conditions : 1. That the membranes are ruptured. 2. That there is complete dilatation of the os and retraction of the cervix. 3. Knowledge of the position of the presenting part. 4. Emptiness of the bladder and bowel.

*What form of Obstetric forceps should be employed?*

The general answer is to use the form best adapted to the case if possible. It must be admitted, however, that each practitioner has acquired by repeated experiences a certain degree of skill in the use of his choice of instrument, notwithstanding its imperfections. But it is not my purpose to refer to the list of instruments which have been more or less in use since the time of Chamberlen's invention, either by condemning one or extolling another, but rather to call your attention to some mathematical principles which should be taken into account in the construction of the obstetric forceps.

It is a trite, but no less true saying that "necessity is often the mother of invention"—with myself it has been the long felt necessity for certain unfulfilled requirements in the obstetric forceps in use that has led to investigations and experiments in this direction. My chief objection to the instruments in use has been the *crossing* of the handles, which, as we are all aware, necessitates the application of the right blade first in order that they may be locked. When the case is one of ordinary position of the head (first position, or left occipito-anterior) there is usually no difficulty in applying the blades in

the regular order ; but it has been my experience, as it has no doubt many times been yours, that when the head is in the second position (right occipito-anterior) or is jammed into the right side of the pelvis, after applying without difficulty the first or right blade of the instrument the introduction of the other was not possible without great risk of injury to mother and child. In every case that I recall, after removing both blades and reversing the order of their introduction no difficulty was encountered till recrossing in order to lock was found impracticable without equally great risks of inflicting injury. An instrument made with the crossed handles reversed would undoubtedly be suitable in these cases, but for ordinary purposes it would not avail.

After much thought and study on this subject, not taking into account the blades, but handles to which any form of blade could be attached, and admitting of the application of either blade first, the instrument which it is my privilege and honor to present for your inspection and consideration is the result. The improvement, as has been said, is in the handles alone, and it is to this that your attention is called.

It was found necessary in constructing such an instrument, in order to avoid the difficulties arising from the crossing of the handles, to do away entirely with this form of handle, and return to the parallel handles improved by the addition of a second joint, and a hand piece so fitted that the necessary traction and compression can be made by a slight effort on the part of the operator.

The force employed is thus a conjoint one effected by means of a double lever, and is everywhere equal in amount to the resistance offered. The amount of traction necessary in the use of this instrument has been found by actual experience both on the manikin and the living subject to be very slight, and the compression just enough to keep the blades from slipping off the head, thus the amount of compression instead of being regulated by the grip of the operator as in the cross-handle instrument, is in every case controlled by the amount of resistance offered, so that in all ordinary cases there is little or no possibility of danger from this source. In certain cases, however, unusual force may be found necessary, and in order to avoid the risk of crushing the foetal head by the increased compression resulting the toggle joint has been constructed so

as to limit the compression to a degree corresponding to that of the average instrument.

As an additional safeguard in malpositions and irregular curvatures of the pelvis, the principal joint is not a fixed one, but allows of slight forward and backward movements of the blades in order that there may be a better adaptation to the head as well as the pelvis ; provision has also been made so that when with other instruments locking would not be possible, these handles may be secured and traction attempted, there being at the same time a slight vertical freedom of the blades to admit of the adjustment to the head becoming more perfect. When the locking can be made absolute from the first this motion does not exist. The advantages then secured in the locking are effected by means of a coned hub with a winged nut attached at the principal joint on the right arm of the instrument.

In twenty-six cases,<sup>1</sup> all of which, undoubtedly, required instrumental delivery, I have used these forceps with results which were indeed surprises, both on account of the facility with which they were applied—either blade first, the slight amount of traction required in all of the cases, and the entire absence of any disfigurement to the children or evidences that in a single instance the compression had been too great.

It is my conviction, gentlemen, that when the obstetric forceps is required the use of this instrument will be attended with fewer risks to the mother, greater safety to the child, and much less difficulty and anxiety to the accoucheur.

## RECENT RESEARCHES RELATING TO THE ETIOLOGY OF YELLOW FEVER.

*Read at the Meeting of the American Public Health Association in Brooklyn, N. Y., October 23, 1889.*

BY GEORGE M. STERNBERG,

MAJOR AND SURGEON U. S. A.

[Abstract for THE JOURNAL.]

The investigation in which I am engaged under instructions from the President of the United States, and in pursuance of authority of an Act of Congress approved March 3, 1887, "making appropriations for sundry civil expenses of the government," is not yet completed. The cultures which I have brought with me from Havana will require further study, and extended comparative researches will be necessary before a definite conclusion can be reached as to the specific etiological relation of one or the other of the micro-organisms which I have obtained from yellow fever cadavers, principally from the intestines.

Owing to the facts mentioned and the limited time at my disposal, I can only give a brief gen-

<sup>1</sup> Since reading the above I have applied the forceps, in all, the thirty-fourth time up to date, with the same degree of satisfaction and success.

eral statement of the present status of the inquiry in which I am engaged and of the methods of research which have been employed. But in my final report a detailed account will be given of the various microorganisms encountered and of the numerous experiments made upon the lower animals.

Having remained in Havana from the middle of March until the first of September of the present year, I have had ample opportunity to obtain all the material necessary for a thorough research by modern culture methods. Thirty autopsies have been made in typical cases of yellow fever, most of which occurred among Spanish soldiers admitted to the military hospital in that city.

My cultures have been made for the most part in flesh-peptone gelatine, and in agar-agar jelly containing five per cent. of glycerine; numerous cultures have also been made in sterilized blood serum, in veal broth, and in *agua coco*. The last mentioned medium I used to some extent during my visit to Havana in 1879, as a member of the Yellow Fever Commission of the National Board of Health. During the past summer I have used it extensively, and find it to be an extremely valuable culture-medium, which is as transparent as water, and yet contains a large amount of nutritive material. It has a specific gravity of 1020 to 1025, a slightly acid reaction, and contains in solution a considerable amount of glucose. Both aerobic and anaerobic cultures have been made in the various media mentioned, into which have been introduced blood obtained from one of the cavities of the heart, material from the interior of the liver, the spleen, and the kidney, urine drawn through the walls of the bladder, and material from the stomach and intestines.

A method which has also been pursued in the entire series of cases consists in the preservation of a piece of liver or kidney, the size of a man's fist, in an antiseptic wrapping, by which the exterior is surely sterilized and the entrance of germs from without is guarded against. Such a piece kept in the laboratory for forty-eight hours as a rule preserved its fresh appearance and had no odor, but upon cutting into it it was found to contain numerous and various microorganisms. The cut surface had a decidedly acid reaction. The microorganisms found under these circumstances were bacilli of various species, and corresponding with those found in the contents of the intestine. They have been isolated by the use of Esmarch tubes and carefully studied. Possibly one or the other of them may be the veritable yellow fever germ, but up to the present time no satisfactory evidence has been obtained that such is the case. The bacilli which have been found most constantly by this method are:

A large, motionless, anaerobic bacillus, resembling in its morphology the bacillus of malignant œdema. This is very commonly present and is

conspicuous by reason of its abundance and dimensions. In my list of microorganisms encountered it is designated by the letter "N."

The *bacterium coli commune* of Escherich, very common.

A motile, non-liquefying bacillus, resembling *bacterium coli commune* in its morphology, but more pathogenic for rabbits and guinea pigs, a facultative anaerobic, very commonly present—my bacillus x.

A short motionless bacillus with stained ends, in chains, resembling the bacillus of Babes, a facultative anaerobic, not pathogenic for rabbits or guinea pigs; found in a limited number of cases only—my bacillus o.

The presence of these various microorganisms in liver obtained at an autopsy made soon after death, and preserved in an antiseptic wrapping, may be taken as evidence that they were present in small numbers at the moment of death, but the examination of "smear-preparations" made immediately after death, and culture experiments made at the same time, show that they are not numerous, and in a considerable proportion of the cases the result of such immediate examination of the fresh liver tissue has been negative.

It is an interesting fact that material from a piece of liver kept as described, and containing the microorganisms referred to, is very pathogenic for guinea pigs when injected subcutaneously in small quantities, 2 to 5 minims, whereas the fresh liver tissue may be injected in considerable amount without producing any noticeable effect. This pathogenic power is due to the microorganisms present, and especially to my bacillus "N" and my bacillus "x." Details of experiments will be given in my final report.

Material from the intestine, also, which contains the same microorganisms is very pathogenic for guinea pigs.

At the close of my address I shall exhibit upon the screen photo-micrographs of the bacilli referred to, and also of the various microorganisms which have been claimed to be the specific germs of yellow fever, viz.:

The micrococcus of Dr. Domingos Freire, of Brazil; his so-called *cryptococcus zanthogenicus*.

The *tetragenus febris flave* of Dr. Carlos Finlay, of Havana.

The liquefying bacillus of Dr. Paul Gibier—my bacillus "g."

I may say with reference to the micrococcus of Freire that I have not encountered it in any of my cultures from the blood and tissues of yellow fever cadavers, and that my extended observations fail to give the slightest support to his claim.

The yellow fever germ of my friend Dr. Carlos Finlay, of Havana, which I have named *micrococcus tetragenus versitilis*, is one of the most common atmospheric organisms in the city of Ha-

vana. I have frequently obtained it in cultures made from the surface of bodies of patients in the hospitals in that city, and also in Vera Cruz, but it is not present, unless by rare exception, in the blood and tissues of yellow fever patients.

The liquefying bacillus which Dr. Paul Gibier isolated from the intestine in a limited number of cases, I have also obtained from the same source in about one-third of my autopsies, but it is not constant, and when present is not abundant. I see no good reason for supposing that it is the specific infectious agent in the disease under consideration.

## THE CLINIC.

### ON BLOOD DISEASES.

BY FRANCIS DELAFIELD, M.D.,

PROFESSOR OF THEORY AND PRACTICE OF MEDICINE AND PATHOLOGICAL ANATOMY IN THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

[Reported for THE JOURNAL.]

#### SIMPLE ANÆMIA.

*Case 1.*—This girl, gentlemen, says that she is 18 years of age; that four years ago, when she was 14 years old, she began to feel sick. When asked in what way she was sick she replied that she felt tired and weak, and her legs were swollen. She also felt sick at the stomach, and threw up sometimes. Her neighbors told her that she looked white. She improved and was better for two months, and then worse again; then she improved again, and has been going on in this way, from better to worse, and from worse to better, ever since. She says that at present she has no headache and is not sick at the stomach. At one time she spat up some blood. Her feet are but little swollen at present. When asked whether she feels any pain, she places her hand over the left side.

The urine has a specific gravity of 1.015; it contains no albumen; it contains phosphates. The blood has been examined; the hæmoglobin is 20 per cent., the blood cells number 1,714,000 to the cubic millimetre. There is a systolic murmur, heard loudest at the second left intercostal space.

We have, then, a case apparently of simple anæmia, but one differing somewhat from the ordinary examples of this disease; differing from them principally in its long continuance and in the severity of the symptoms. Yet, after all, there is nothing in the history of the case to take it out of the class of simple anæmias.

The girl, as some of you have heard her say, is 18 years old now, and she began to have the same symptoms which she has now four years ago. Those symptoms have continued during a large part of the entire four years. They are observa-

ble in a marked degree at the present time. They have been the ordinary symptoms of simple anæmia in young women. There is the pallor of the face which we should expect to find; there has been headache, disturbance of the stomach, nausea and vomiting, constipation; and there has been disturbance of the menstrual function, consisting in irregularity and scantiness of the flow. There has been the disposition to dropsy, cedema of the legs occurring as far back as four years ago, but not present in any marked degree now. The disposition to bleeding has been present in slight degree. In her case apparently it has not been from the stomach. She has coughed up a little blood from time to time. Whether the blood comes from the throat, the bronchi or the trachea, we do not know; but the disposition to bleeding from the mucous membranes belongs to the disease. We do not know whether she has had any febrile movement. It is very probable she has had, for in marked anæmia there is very apt to be some febrile movement.

When we come to the actual condition of the blood at the present time we find it about as bad as it is likely to be in these cases of simple anæmia. The hæmoglobin is 20 per cent. We sometimes find it down to 18 per cent. in cases of simple anæmia, but 20 per cent. is a very small proportion, and it means a very well marked case of the disease. In the same way with the red blood cells; it is quite possible in milder cases of simple anæmia to have no diminution of the red blood cells, although the quantity of the hæmoglobin is decreased, but the moment we meet the more severe cases we find also a diminution in the number of the red blood cells. In this case the number is diminished in a very marked degree; it is below 2,000,000, instead of being 5,000,000, in the cubic millimetre.

So that we have both an old and a very decided case of anæmia, yet I should have no hesitation in saying that it is one of simple anæmia, although the disease has lasted so long, and the changes in the blood are so marked at the present time. I should not consider it a case of pernicious anæmia. The difference in the prognosis is very great in these two conditions. If this girl has only a simple anæmia she will get well; if she has pernicious anæmia she will not get well. So that the importance of the diagnosis as regards the prognosis of the case is very great indeed. But, as I said, I should have no hesitation whatever in pronouncing her case one of simple anæmia, and in asserting that, if placed under proper conditions, she will get well. I should feel quite certain of it, and I imagine that the only reason why the disease has continued so long is simply the want of proper treatment. The girl has kept about; she has probably consulted a physician from time to time, has been under treatment for a short time, and then, without getting really better, has gone

back to work, and thus the condition has been protracted during all these years.

For this girl to get better, she must have the proper treatment, and she must also live in the proper way. The medicinal treatment is very simple. It consists in the administration of iron in large quantities, usually in the form of Bland's pills, which contain the sulphate of iron. We give these patients of Bland's pills anywhere from six to twenty-four a day. They should receive enough; a small quantity is of no service.

Besides the administration of iron in large quantities you should have the patient inhale oxygen gas ten or fifteen minutes twice a day. In the third place, the bowels must move every day, which may be induced by an enema or some simple laxative. That constitutes the medicinal part of the treatment, and it is exceedingly efficacious. Yet, after all, it is altogether empirical. We do not know why it is that these large quantities of iron are so useful. It evidently cannot be by simply supplying the patient's blood with iron, for we have to give a great deal more than is necessary for this purpose. So of the inhalation of oxygen, I do not think that theoretically very much can be said for it, but practically it is a very important part of the treatment. Then, again, with regard to the constipation—of course anybody is better off for not being constipated, but it makes a greater difference with these patients with anæmia whether they are constipated or not than it does with others. If they remain constipated you do not get the good effects which you ought from iron and oxygen. Thus with regard to these three points in the medicinal treatment, each one of them is empirical; we do not know as well as we would like why the patients improve under them, yet every day's experience shows how much they do.

As to the feeding, I should put this patient upon one solid meal a day, composed of meat and of bread and butter, and during the rest of the twenty-four hours I would feed her on milk alone.

With regard to the mode of life: as this girl is now, I should put her to bed. She is too sick to be up and about. She will improve more rapidly for a time if in bed than if she is allowed to be up. By and by, after the blood had begun to improve, she could begin to get up and go about. Now, all this can probably be done for this girl if she enters a hospital, and that will be the best place for her. It will take, probably, two or three months before she will be well enough to go to work. By the end of two or three months, one can say beforehand with considerable certainty, that the blood will have changed in about this way: Instead of having 20 per cent. of hæmoglobin, it will have about 80 per cent. She will not come up to the normal, but she will have 80 per cent. instead of 20 per cent. Instead of having 1,714,000 red blood cells to the cubic centi-

metre she will have between 4,000,000 and 5,000,000. The blood will have returned to nearly its natural condition; the other symptoms will have disappeared. There will no longer at that time be any disposition to nausea and vomiting. There will be no disposition to bleeding, she will no longer be short of breath, she will feel strong and well, and able to go to work. That is what we can promise in such a case with very great confidence. But this case being an aggravated one, it is necessary that all parts of the treatment should be carried out. It will not be enough to give this girl some iron and let her go to work. She needs rest in bed; she needs diet, besides iron, oxygen, and enemata to relieve constipation.

#### PERNICIOUS ANÆMIA.

*Case 2.*—This old gentleman was at our clinic on March 21, 1889, and the diagnosis at that time was, not of simple anæmia, but of pernicious anæmia. The examination of the blood then showed that hæmoglobin was down 15 per cent.—a very small quantity. The red blood cells were down to 1,662,000—after all not very much less than in the girl who has just gone out. Taking the man as he was last March and the girl as we have seen her to-day, and there is not very much difference in the composition of the blood in the two cases. In the man the hæmoglobin was 15 against 20 in the girl, and 1,662,000 red blood cells against 1,704,000. There was no increase in the white blood cells at that time.

He was put upon the use of tincture of chloride of iron and of arsenic. On the 21st of March the treatment was begun, and on the 5th of April the hæmoglobin had got up to 22 per cent. On the 20th of April it was 27 per cent., on the 25th it was 22 per cent., and on the 7th of May it was 28 per cent. On the 13th of May the red blood cells had increased to 2,425,000, and the hæmoglobin had increased up to 40 per cent. Thus you see that there was a very substantial improvement in the condition of the blood under the administration of iron and arsenic, from 15 up to 40 per cent. of hæmoglobin, and from one million odd up to two million odd of red blood cells. During this time the man had no fever, and no hæmorrhages. He felt so much better that he went back to his work, and continued to work until a month ago. Then he came back to the clinic with a return of the same symptoms, but much weaker.

The examination of the blood made to-day, shows that the hæmoglobin is 20 per cent., and that the red blood cells are below 1,000,000, in fact down to 300,000. That is a very small number, indeed. It is not often we get below 1,000,000 to the cubic millimeter. The urine has a specific gravity of 1.015; it contains no albumen and no sugar.

Now, this man presents about the same symptoms as the girl we just saw. The changes in the blood are of about the same kind, only differing in degree. Like her, he has had loss of strength, dyspnœa, and other symptoms, but he has not had a disposition to bleed. Although the clinical history was much the same in the two cases, yet I had no hesitation when I saw this man in March, in saying that he had pernicious anæmia instead of simple anæmia, and there is still less reason for doubting that diagnosis at the present time.

Now these cases of pernicious anæmia are sometimes capable of temporary improvement, but the rule is that the improvement is not only temporary, but it never goes beyond a certain point. The blood does not get anywhere near back to the normal. It gets better, but it does not get anywhere near the normal; and after improving for a time, the condition of the blood begins to grow worse, and the patient's general condition changes for the worse.

The treatment of these patients then is not nearly as satisfactory as the treatment of the cases of simple anæmia. The iron alone seems to do them but little good. The drug that we rely most upon is arsenic; arsenic given in considerable amount during the twenty-four hours. Although the administration of arsenic constitutes the principal part of the medicinal treatment, yet there also seems to be an advantage in adding to it iron, the inhalation of oxygen, and something to relieve constipation if it exist.

Here, again, the treatment is altogether empirical. We know of no very good reason why arsenic should be of benefit to these patients; we know of no very good reason why iron should not be of as much use to these patients as it is to patients with simple anæmia; nor do we know of any very good reason why oxygen should not be of as much use to these patients as in cases of simple anæmia. But a very little experience will show you the practical difference, that the cases of simple anæmia get well under a certain plan of treatment, and that the cases of pernicious anæmia never do anything better than improve somewhat and then get worse again; and each time that they get worse they are worse than they were the time before.

It is very commonly believed that in simple anæmia the change in the blood is due to a diminished formation of red blood cells and a diminished production of hæmoglobin, and that in pernicious anæmia the cause of the change in the blood is increased destruction of the red blood cells. One observer in particular has gone so far as to locate the place of destruction of the red blood cells in pernicious anæmia in the liver. He believes that in that organ there is constantly going on an excessive destruction of the red blood cells, and that that is the reason for the

change seen. All these considerations, however, are so far theoretical; but of one thing we can be certain, and that is the practical difference between a case of simple anæmia and one of pernicious anæmia. But here, again, there are a good many physicians who believe that pernicious anæmia is practically nothing but a bad simple anæmia; that if you have simple anæmia bad enough, you can be said to have pernicious anæmia. This I do not think is true. I think the two conditions are absolutely separate and have nothing to do with each other. At all events, for practical purposes we find that the prognosis and the effects of treatment are altogether different in the two cases. I would advise this man to enter the hospital again.

After the patient had left the room Dr. Delafield continued:

I am very much afraid, however, that when he goes into the hospital this time he will remain there. He has reached the period of his disease now at which we are not likely to get even temporary improvement. With such an excessive diminution in the number of the red blood cells I should not hope for any real improvement at all. The man can be made comfortable, but that is all. I should suppose that he would not be likely to live through the winter. He may be carried off by some intercurrent disease, to which he is more liable than other persons; or he may die, as some patients do, simply in a condition of very great feebleness.

#### PSEUDO-LEUCÆMIA (?)

*Case 3.*—This young woman was sent to the clinic as a case of pseudo-leucæmia, or Hodgkin's disease. She says she has been unwell eight months. We observe a tumor near the angle of the inferior maxilla on the left side, which, she says, has been present about two years. It is an enlarged lymphatic in that part of the neck. Some of the other glands in that region are also enlarged, but they do not extend beneath the clavicle. Those on the other side are not enlarged. She says that eight months ago, or in March last, she began to suffer from pains which she describes as commencing in the region of the sacrum and radiating down to the knees, both in front and back. Sometimes a week would pass when she would not have the pains; then they would come on and continue day and night. She vomited at times, and then would lose her appetite; at other times her appetite has been pretty good. She has been troubled with dizziness a good deal, and has been short of breath, but she says she has not coughed and has not spat up blood. There was no swelling of the feet. She remained in bed most of the time from last March until two months ago. She lost flesh, but is now much better than she has been. Her blood has been examined to-day. The percentage of hæm-

oglobin is 65. There is no increase in the number of the white blood cells; the count of the red blood cells has not yet been made. For two weeks she has been taking Fowler's solution, three minims up to seven minims seven times a day.

I doubt whether one would be justified in classifying this case among those of Hodgkin's disease. There seems to be no affection of the glands except those in the neck. This tumor, by the by, ought to be removed. It is very loose and movable; the deeper glands are not large or numerous, and I think there can be no question but it would be wise for her to have it removed as soon as possible. It is quite independent, it seems, of her other troubles. Such glandular enlargements are never good things to have and should always be removed, especially when it can be done as readily as in this case. My assistant had examined the other glands of the body and did not find them enlarged. Two weeks ago he thought he was able to make out some enlargement of the spleen, but he is no longer able to do so.

The history is just one of those which we get now and then, especially from women, in which we find it very difficult to tell how much attention to pay to the symptoms which they lay most stress upon. She had nothing to attract her attention until two years ago, when she noticed an enlargement on the lower part of the face, which went on to increase in size, and is evidently an enlarged gland, due either to simple or tubercular adenitis. She went along with this enlarged gland, but feeling perfectly well, until last March. Then she felt so weak that she went to bed, and she began to have severe attacks of pain which, so far as I can make out from her statement, began in the sacrum. From there they would extend down the thigh, but not following the course of any particular nerve; she felt them, she said, throughout the entire thigh down to the knees. When she had these attacks of pain she also had vomiting and inability to take food. When she did not have the pains she did not have to vomit. Sometimes she would have the pains every day, sometimes she would skip a week, and lately she had not had them for a month or so. The attacks of pain, the weakness, and the disturbance of the stomach seem to have been the prominent symptoms. Two months ago she got a little better, but not much. Then she came here to the dispensary and has been coming seven weeks. She was given arsenic, and during her attendance at the dispensary she has improved a good deal. She now feels a good deal better.

When we look at her the general appearance is not particularly bad. She is flushed, of course, with the excitement of being here, but her color is not bad. She is in moderate flesh; she says she has gained in weight lately. There is nothing

to call attention to the heart, lungs, or any of the viscera. The heart's action is rapid, but there is no murmur.

This is a sort of case which is more common in private practice than it is in cases which we see here. I should be disposed to class it with the patients, especially women, who suffer a great deal, sometimes in one way, sometimes in another, without really having any definite disease of any part of the body. I do not mean to say that the sufferings of these patients are imaginary; they are perfectly real. They are sick; they require treatment; and yet you can not ascribe the sickness to any of the ordinary categories. They are very often somewhat anæmic; they have a diminution in the quantity of hæmoglobin, but yet they are not typical cases of simple anæmia. They do not behave in the same way, by any means. There is a change in the composition of the blood; but, as said, they do not fall into the class of cases of simple anæmia. When they have pains they are very apt to have them as this young woman has had them—in the wrong place; I mean the place that does not belong to any of the regular kinds of pain. Instead of having pain beginning in a particular place and behaving in a way which pains do that belong to diseases we know of, they get up some queer irregular pain, as in this girl. It hurts as much, evidently, yet it is equally evident that it does not belong to the pains which have a real cause. I mean by real cause something like inflammation of a nerve or of bones, or pressure upon a nerve. It is evident from this young woman's description that her pain can not be due to any such cause as that; it is one of the cases of irregular pain.

Of course, to be at all certain about such a case as this you should see it more than once. You should ask a good many questions which I do not care to ask her here. The moral condition comes into play largely; and so far as treatment is concerned, they are cases for management rather than anything else—the moral management, the regulation of the diet and of the mode of life. The particular medicine which you give them is not of so much consequence, so long as it is not opium or bromides (or the different drugs given for nervous troubles). The change in the blood, the anæmia which these patients have, does not, as a rule, respond very readily to the use of iron; it responds much more readily to the mode of life, to diet and exercise. Nor does it respond very well to the use of arsenic. This drug is sometimes of service, sometimes it is not. Since it seems to have been of benefit in this case we will continue it.

#### MALARIAL POISONING.

*Case 1.*—The case of this young man is a perfectly straightforward one of malarial poisoning. He works on board one of the steamers which

ply between here and the West Indies, stopping at different points, for a longer or shorter time, where the severer forms of malarial disorders prevail. He was in a hospital at Jamaica, but got better and came out again. His illness dates back seven weeks; during more or less of this time he has had headache, has vomited, has not cared for his food, has felt hot, but has not had chills. His temperature was taken five days ago, when it was  $102^{\circ}$  F.; to-day it is  $98^{\circ}$ . His urine has a specific gravity of 1.025; it contains no albumen. On physical examination we find his spleen distinctly enlarged; the liver, on the other hand, is not enlarged. His blood has been examined and found to contain a large number of crescent-shaped pigmented bodies.

The man has acquired not intermittent nor remittent fever, but a form of malarial poisoning which we commonly call malarial cachexia, in which the main change is in the general condition of the patient. Such patients may have a little fever, but it is not a prominent symptom. They lose flesh and strength, and they may have the characteristic changes in the blood.

## MEDICAL PROGRESS.

**CHRYSAROBIN IN HÆMORRHOIDS.**—DR. KOSOBUDSKI, writing in the *Russkaya Meditsina* on Unna's plan of treating hæmorrhoids with chrysarobin, says that he has employed it—or a modification of it—in twenty-two cases, and has found it on the whole very satisfactory. He does not, however, employ quite such strong preparations as Unna. His plan is to wash the hæmorrhoid with a weak carbolic or creolin lotion, and then to dry it well with cotton wool, after which he applies three or four times a day an ointment consisting of chrysarobin 8 parts, iodoform 3 parts, extract of belladonna 6 parts, and vaseline 150 parts. For internal piles suppositories are employed, which are composed as follows: Chrysarobin, 1 grain; iodoform,  $\frac{1}{4}$  grain; extract of belladonna,  $\frac{1}{8}$  grain; cacao butter, 30 grains; glycerine sufficient to enable the mass to be made into the form of a suppository. If there is much hæmorrhage a tannin suppository must be used. After three or four days of this treatment the pain and hæmorrhage disappear, and after three months or so the hæmorrhoids are found to have almost completely shrivelled up.—*Lancet*.

**PARATYPHLITIC ABSCESS.**—DR. J. F. JENKINS, of Tecumseh, Mich., at a meeting of the Michigan State Medical Society, related a case of paratyphlitic abscess. Paul P., æt. 10 years, had an attack of paratyphlitis in December, 1886, following catarrhal pneumonia. In fact, before

he began to convalesce from the pneumonic trouble, the symptoms of paratyphlitis began to manifest themselves. He was at that time confined to the bed about three weeks with the disease, which eventually terminated in resolution.

The patient enjoyed good health until June 2, 1888, when Dr. Jenkins was again called to see him. He complained of pain in the right iliac region, and in that locality pressure elicited a great deal of tenderness. The bowels were constipated, and during the course of the disease there was more or less tympanites. There was occasionally a slight degree of nausea, but he seldom or never vomited. Disuria was troublesome at various periods of his illness, and during the same period priapism was occasionally observed. The right thigh was flexed upon the body during the course of the disease. This was a marked condition in the first attack. He frequently complained of pain extending from the hip to the knee. The pain in the bowels was never severe, and only required a limited amount of anodynes to control it. The temperature ranged from  $100^{\circ}$  F. to  $103^{\circ}$  F. He seldom or never complained of being chilly. During his illness his appetite was moderate and he slept tolerably well.

July 19, nearly seven weeks from the date when his illness commenced, the patient was placed under chloroform by Dr. L. G. North. Dr. Jenkins brought the right limb, which had been flexed, into a straight position, which revealed an elongated tumor in the iliac fossa about the size of a walnut; and by the use of the hypodermic syringe, demonstrated the fact that the tumor contained pus. He made an incision into the tumor, and nearly eight ounces of very offensive pus was evacuated from it. A moderate sized drainage tube was introduced and extended to the bottom of the cavity of the abscess. It may be well to mention here that this cavity was never rendered aseptic. The patient henceforth rapidly recovered, notwithstanding the weather at that season of the year was extremely warm. This boy only a short time since passed through his third attack of paratyphlitis, and the formation of the second abscess, the symptoms being similar to the previous attacks already mentioned.

His illness commenced on April 1, of this year, and a week from that date, he was again placed under the influence of chloroform by Dr. North, and an incision made into the abscess, and the contents evacuated. Dr. Jenkins then introduced his finger into the cavity in order to determine whether there was anything that he could detect, which produced the abscess, but with a negative result. It was afterwards carefully washed out with carbolized water, and a drainage tube inserted deep enough to reach the bottom of the cavity. During several days afterwards it was

syringed out with carbolized water, and ten days after evacuating the abscess the wound healed and the patient was able to sit up.

The abscesses above described and operated upon, were extra-peritoneal. The first abscess was not operated upon until nearly seven weeks had elapsed from the commencement of the attack of paratyphlitis; from the fact that the parents would not consent to an earlier operation. The principal factor in producing this Fabian policy in their minds, and in Dr. Jenkin's, was that the first attack of the disease terminated in resolution, after an illness of three weeks. The second abscess was opened on the seventh day from the commencement of the attack, and the patient made a rapid recovery.

The great difficulty is to diagnose between an extra- and an intra-peritoneal abscess. In either case it is an all important factor to determine when to operate. The history of the case, the condition of the patient, the use of the hypodermic syringe, or the aspirator, will go far in determining the necessity of an operation which, in many cases, if performed sufficiently early, will in all probability save the life of the patient, or on the other hand, by prolonging the date of an operation may jeopardize his life.

**DISINFECTION OF THE BIRTH-CANAL.**—In order to secure complete disinfection of the vagina and cervix, DÖDERLEIN and GÜNTHER have made many experiments. The employment of simple mechanical measures, such as scouring with the finger and irrigation with sterilized water, has proved inadequate. The finger anointed with vaseline to enable it to reach the various vaginal folds, has given no better results. Irrigation with solutions of sublimate and carbolic acid have only produced incomplete disinfection, while they have the disadvantage of leaving the mucous membrane dry and harsh. Contrary to Steffek (who does not like creoline), the writers have obtained their best results with creoline. Their method is to anoint the finger with a lubricant mixed with creoline, and then rub and scour carefully the mucous membrane of the genital passages with it. This is followed by copious injections of a 2 per cent. solution of creoline. After this operation the mucous membrane remains soft and supple, while the vagina has always been found to be free from all germs.—Maygrier, *Rev. des Sc. Méd.*

**TREATMENT OF SYPHILIS BY SUBCUTANEOUS INJECTIONS OF MERCURIAL PREPARATIONS.**—H. LELOIR and M. A. TAVERNIER have administered, during the last two years, 1573 injections in the treatment of syphilis. The cases were treated as follows: Eight hundred and seventy-five with calomel in suspension in vaseline oil (1 to 12); 642 with the yellow oxide suspended

in oil of vaseline (1 to 12); 56 with gray oil according to Neisser's formula (vaseline oil 40, ethereal tincture of benzoin 5, purified mercury 20).

The injections of calomel and the yellow oxide (half a Pravaz syringeful) were repeated every eight days, the needle being thrust deeply in the muscles of the fossa behind the trochanters; the injection of the gray oil (one-third of a syringeful) was given every nine days in the buttocks. The punctures were covered with mercurial plaster. These injections are especially useful in cases of erythematous eruptions or the eruptions of resolving syphilomata on the integument; they possess the sole merit of acting rapidly, not to say harshly. Their action upon mucous surfaces is almost *nil*. They are more apt to be followed by recidives than are inunctions, and are less certain than the latter in their effects. They should not be used in non-resolving syphilomata in cerebro-spinal and visceral syphilis, or in cases of pregnant women or in children. They are especially applicable in the treatment of prostitutes, while in ordinary private practice their use is attended with serious inconveniences.—*Gazette Méd. de Liège*.

**HYDRASTIS IN MEMBRANOUS DYSMENORRHOEA.**—DR. FRANZ JORDÁN relates in a Hungarian medical journal an interesting case of most obstinate membranous dysmenorrhœa, in which after many years had been spent in trying all manner of different methods of treatment, hydrastis canadensis rapidly effected a cure. Dr. Jordán employed the liquid extract of hydrastis canadensis, twenty-five drops of which he ordered twice a day. This very soon began to produce an appreciable effect, and after a short time the medicine was required only at the time of menstruation or for a few days previously, the loss of blood becoming very light, and the pain disappearing altogether.—*Lancet*.

**DISINFECTION OF SICK ROOMS.**—According to KELDYCH (*Journal de Méd.*, Sept. 22, 1889), an adequate disinfection of rooms may be secured by saturating the air with eucalyptol, a disinfectant that is not dangerous to inhale, and that has no injurious effect upon furniture. Keldych has shown that an examination of the air of clinical lecture rooms, when thus treated, proves it to be free from bacteria which can be cultivated upon gelatin. Moved cultures can still be produced, but the action of these upon the higher animals, though not well understood, appears to be harmless.

**PRECOCIOUS MENSTRUATION.**—DR. A. J. JAGOE, of Hernando, reports the case of a child four years of age who has been menstruating for two years. The child, a negro, was exhibited at the local Medical Society and found to be healthy; its breasts are well developed and the pubes covered with hair.—*Memphis Med. Monthly*.

PUBLISHED WEEKLY.

SUBSCRIPTION PRICE, INCLUDING POSTAGE.

PER ANNUM, IN ADVANCE.....\$5.00  
SINGLE COPIES.....10 CENTS.

Subscription may begin at any time. The safest mode of remittance is by bank check or postal money order, drawn to the order of THE JOURNAL. When neither is accessible, remittances may be made at the risk of the publishers, by forwarding in REGISTERED letters.

Address

JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION,  
No. 68 WABASH AVE.,  
CHICAGO, ILLINOIS.

All members of the Association should send their Annual Dues to the Treasurer, Richard J. Dunglison, M.D., Lock Box 1274, Philadelphia, Pa.

LONDON OFFICE, 57 AND 59 LUDGATE HILL.

SATURDAY, NOVEMBER 30, 1889.

A NEGLECTED PHASE OF ENURESIS NOCTURNA.

So much is continually appearing in medical journals on the subject of enuresis nocturna, and so many remedies are being recommended as wholly reliable and efficacious in its treatment, that it would appear almost superfluous for us to refer to it. And yet, if we examine all this literature, we will see that it has a very one-sided

bromides or other sedatives; so that, in consideration of the prejudicial manner in which this subject is generally treated, it seems that there is still room for discussion directing our attention more in the channel of a judicious inquiry into its causation and pathology, which naturally calls for a clear perception of the anatomy and physiology of the parts.

First with regard to the mature type, as presented by the adult male.

The detrusor and sphincter muscles of the vesical system are innervated from two sources: The detrusors, those contained within the bladder walls, are supplied from the sympathetic system, and are, therefore, involuntary; the sphincters, two in number, of which the external is formed by the compressor urethræ (A, fig. 1), the internal by the ring of muscle making up the base of the prostate (B, fig. 1), are supplied from two sources: the external one is supplied entirely from the spinal cord, and is, therefore, entirely voluntary; but the internal or prostatic sphincter, while possessing some voluntary fibres, is composed mainly of involuntary muscle. As a result of this the process of collection and voidance of urine is carried out in this way: We will imagine fig. 1 to represent an empty bladder,

FIGURE 1.

FIGURE 2.

aspect; that (except in cases arising from reflex irritation or organic lesions, whose treatment is indicated by the discovery of such a cause—a class which we do not propose to consider here) nearly all of the remedies advised are used either empirically, or their use is based on the idea that the origin is invariably, as Trousseau declared, a neurosis, an excessive irritability, or exaggerated tonic of the muscular fibres of the bladder, subservient to a hypersensitive condition of the mucous membrane of the organ; and the little sufferers are accordingly dosed in progressively increasing quantities with belladonna, atropia,

Both sphincters are then closed and the point of separation between the bladder cavity and the urethra is clearly defined. But as urine accumulates in the bladder, it gradually lifts up and distends the vesical walls until the amount of distension reaches a certain degree, when the urine pressure becomes sufficient to divulse, to a slight extent, the urethral opening, allowing some of the urine to trickle into this prostatic portion, soon distending it also. It is then that the desire to urinate is first felt. But if it is not convenient for the person to answer the call at that time, his

will acts on the sphincter—the external one more especially—which remains contracted until such time as he is willing to pass his water. Then the bladder is in a condition about like Fig. 2, and the cavities of the prostate and bladder are merged into one. When the person does wish to pass his water, the external sphincter and that part of the prostatic muscle located at its apex relax their vigil and open up a passage for the urine.

That all this is true may be proved in various ways, the simplest being to introduce a catheter when the bladder contains only a small amount of urine, mark the length of the catheter within the urethra just when the first drops of urine appear, then wait till the bladder is quite full and repeat the experiment, when it will be found that fully three-quarters of an inch less of tubing will be required now to “strike water” than was necessary in the first experiment, showing the shortening of the urethra in consequence of the encroachment of the bladder cavity on it. So that the power of voluntarily holding a bladderful of urine depends not so much on the strength of this internal sphincter as it does on the strength and amount of control which the person has over the external one. But, on the other hand, that the external needs the support and reinforcement of the internal or prostatic sphincter, is proved by the very affection under discussion.

In early infancy the retentive function is almost *nil*, and incontinence is therefore natural, physiological. Later, in childhood, the boy is educated up to and practices control over his sphincter, the external voluntary one, the only one as yet in working order, which he manages very well during the day, when urination is frequent and calls are promptly met; but at night, when his will-power is banished in the land of dreams, the urine surprises the slumbering sphincter, steals past it and escapes into the bed. But with the development, towards puberty, of the prostatic tissue and the accession of involuntary sphincter action, such incontinence, whether nocturnal or diurnal, ceases; the involuntary comes to the assistance of the voluntary, bears its share of the burden, and the infantile annoyance becomes a nonentity. Should it persist after this epoch, we must attribute it to a continued weakness or lack of development on the part of one or both of the sphincters.

But it may be contended that this is not necessarily so—that the hyperexcitability first referred to will explain this phenomena equally as well. What do we know about “hyperexcitability” or irritability of the bladder? That wherever there *is* such a condition, it manifests its presence in unmistakable terms. There is frequency of urination, by day as well as by night, with pain that admits of no dallying when the call to urinate is felt. What man with an inflamed or irritable bladder-neck dares to disregard the signal of accumulated urine?

On the other hand, do we hear the little subjects of nocturnal incontinence make any complaints of this sort? If we listen attentively to his or his mother's description of the trouble, we will probably soon disabuse ourselves of pre-formed ideas of excitability, etc. The complaint is simply of an *inability to hold water*. There is no pain, no urgent desire to urinate, other than that produced by the remembrance that unless he take the proper care, the consequences of parental wrath will follow the soiling of his clothes.

To be sure, we must admit that there are some cases for which irritability, in consequence of hyperacidity of the urine, or some such transient condition, must be held accountable, but such cases are as short-lived as their causes, and are not to be classed with those under discussion.

Concluding, then, that enfeeblement of the retentive powers is the *raison d'être* of the malady, our object should naturally be to combat this defect. The administration of strychnia, rhus aromatica, ergot, etc., probably has a certain value in this respect; but the remedy, reliable above all others, and the one that has done much to substantiate the views just presented, is that of electricity, applied not by placing one pole on the perineum and the other on the abdomen, in the vague hope that, guided by a kind Providence, the current may pass through the enfeebled muscles; but it should be conducted *through* them by means of an insulated electrode introduced into the urethra after the manner commonly employed in treating strictures with electrolysis. GUYON, the originator of this method, directs that each séance be not longer than two or three minutes in duration, and not too frequent. Only the sphincters are to be galvanized. The female urethra, surrounded as it is by sphincter muscle throughout its extent, is treated by passing the

electrode slowly back and forth from meatus to vesical neck.

Successes with this method, in both male and female patients, have been obtained and reported by GUYON,<sup>2</sup> JAMIN<sup>3</sup> and others, whose names we do not now recall, and success in each case was forcibly emphasized by previous records of repeated failures with other established and approved plans.

We do not wish to be understood as advocating this as an invariably appropriate treatment for infantile incontinence, but our object is simply to express a belief that it is too little used in many cases in which close questioning and a definite diagnosis would point to it as the only rational method.

#### THE TOPICAL TREATMENT OF DIPHThERIA.

There is a widespread and seemingly well grounded belief in the primarily local nature of diphtheria. If the belief be true, local treatment is demanded, and that at the earliest possible moment. And although the question of the local nature is one of great importance, the practitioner ought not to permit his own skepticism to master his method of treatment. Much of the danger inherent in the disease lies in the possible extension of the diphtheritic process into the lower respiratory passages. If, therefore, there is a method of topical treatment which will arrest the development of membrane and prevent its extension without doing injury to the patient, that remedy should be employed in every case. The doubt which exists in the minds of some practitioners as to the possibility of attaining this end, and the diversity of opinion among others as to how the end may be attained are, in one sense, unfortunate; but they have no doubt had the effect of stimulating investigation.

Almost every remedy and every conceivable combination of remedies has had its advocates. Lunar caustic, one of the earliest applications, is now seldom employed, except at the commencement of the disease when the membrane is yet very limited in extent. MORELL MACKENZIE pronounces caustics dangerous and astringents harmful, and prefers as a topical application a solution of chloral hydrate. Corrosive sublimate, the best of all parasitocides, should, *a priori*, be the best agent for local application, and it has of

late been used by many with much success, but it must obviously be used with due caution.

In the *American Journal of the Medical Sciences* for November, MULHALL, of St. Louis, proposes washing out the throat with about a cupful of an antiseptic solution by means of an ordinary household syringe at intervals not exceeding three hours in length. A diluted mixture of carbolic acid and compound solution of iodine is recommended as best suited to the purpose. The author asserts that the method of treatment may be practiced with impunity even on very young children; but we should fear for the result in less skilful hands.

DETHIL's treatment with turpentine, tar and resin should not be lost sight of, for we have combined in it both local and systemical treatment of the patient, and disinfection to some extent of the apartment or the entire dwelling. A more agreeable if not more efficient mode of procedure is that of J. LEWIS SMITH, who recommends the constant ebullition of a mixture of eucalyptus oil and turpentine in the proportion of 2 drachms to 8 ozs. in a quart of water. SCHMIEDLER has more recently practiced the local application of pure turpentine.

We have repeatedly seen permanent arrestation of all throat symptoms follow the thorough application of the solution of subsulphate of iron (Monsel's solution), as practiced by WHITTAKER, of Cincinnati, and reported by him in 1881, after its successful use in a series of nineteen cases. The method consists in passing a brush or pledget of cotton saturated with the solution up into the post-palatine space, permitting the spontaneous muscular contraction which follows to express the medicament, thus causing an inundation of the entire mucous membrane. The application is attended with no danger of injuring the mucous surfaces and is followed by no more serious consequences than retching and sometimes vomiting. In this application we have probably the combined action of an astringent and a parasiticide. As an astringent, its use is indicated to retard the growth of membrane and to prevent the absorption of ptomaines. As a parasiticide, it is directed against the supposed cause of the disease. Whittaker is quoted as having recently reiterated to the Academy of Medicine his confidence in the method. Favorable reports have appeared from other sources also, rendering it highly proper that the remedy should receive a thorough trial.

## EDITORIAL NOTES.

## HOME.

**HYGIENE AND PHYSICAL CULTURE AT GETTYSBURG.**—The parents of the late Dr. Charles H. Graff have donated the sum of \$25,000 to the Pennsylvania Hospital, Gettysburg, for the purpose of endowing a professorship of hygiene and physical culture in that institution.

**SOUTHERN GYNECOLOGICAL ASSOCIATION.**—The Southern Surgical and Gynecological Association closed its annual session in Nashville, Tenn., on the 14th inst. The next meeting will be held in Atlanta, Ga. Dr. George J. Engelmann, of St. Louis, was elected president; Dr. B. E. Hadra, of Galveston, Texas, first vice-president; Dr. Duncan Eve, of Nashville, Tenn., second vice-president; Dr. W. E. B. Davis, of Birmingham, Ala., secretary, and Dr. Hardin P. Cochrane, of Birmingham, Ala., treasurer.

**THE CENTRAL TEXAS MEDICAL ASSOCIATION** will meet in Waco, Tuesday, January 14, 1890, for which meeting the following programme has been appointed: "Cerebro-Spinal Meningitis," by Dr. J. C. J. King; "Pneumonia," by Dr. C. T. Young; "Hæmorrhoids," by Dr. J. E. Brown; "Cystitis," by Dr. W. C. Blalock; "Diseases Incident to Dentition," by Dr. J. M. Witt.

**NORTH TEXAS MEDICAL ASSOCIATION.**—The next meeting of this Association will be held in Gainesville, Texas, beginning on Tuesday, December 10, 1889, and continue for three days. The meeting will be called to order promptly at 7:30 o'clock P.M. The arrival of the trains late in the afternoon occasions the selection of this hour, in order that valuable time may not be lost. The following programme has been issued:

*Section on Practice of Medicine.*—"Exophthalmic Goitre," by Dr. T. M. Taylor, Sherman; "Valvular Lesions of the Heart," by Dr. M. C. McBride, Lebanon; "Acute Articular Rheumatism," by Dr. J. D. Bedford, Honey Grove.

*Section on Obstetrics and Gynecology.*—"Puerperal Fever," by Dr. O. H. Caldwell, Dodds; "Diagnosis and Treatment of Pelvic Cellulitis," by Dr. J. E. Gilcreest, Gainesville; "The Most Desirable Position for a Woman in Labor," by Dr. Alonzo Sims, McKinney.

*Section on Surgery.*—"Traumatic Cataract," by Dr. R. H. Chilton, Dallas; "The Indications in the Surgery of the Larynx and Trachea," by

Dr. E. W. Rush, Paris; "Surgical Cases, Including Two Cases of Laparotomy," by Dr. J. M. Inge, Denton.

*Volunteer Papers by Request.*—"A New Artificial Drum Membrane," by Dr. H. N. Spencer, St. Louis; "Herpes Progenitalis," by Dr. G. Frank Lydston, Chicago, Ill.; "Extirpation of the Ileo-Cæcal Junction," by Dr. J. F. Hooks, Paris; "Cerebro-Spinal Meningitis," by Dr. S. D. Moore, Van Alstyne.

## FOREIGN.

**DR. G. GRANVILLE BANTOCK** has been elected an Honorary Fellow of the American Association of Obstetricians and Gynecologists.

**FIRST AID IN THE ITALIAN ARMY.**—The Italian Minister of War has requested the medical department to draw up a programme of instruction in the elements of medicine and surgery suitable for use in military schools. It is intended that all cadets and non-commissioned officers shall make themselves competent to give first aid in cases of accident and other sudden emergencies.

**THE AMERICAN HOSPITAL AT TEHERAN.**—The United States Minister to the court of the Shah, recently laid the corner stone of an American hospital at Teheran. The funds for its erection have been raised partly in the United States and partly in Persia. Dr. W. W. Torrence, of Teheran, was the originator of the movement.

**THE SCIENTIFIC GRANTS OF THE BRITISH MEDICAL ASSOCIATION.**—We learn from its official organ that Dr. Sidney Martin has, on the recommendation of the Scientific Grants Committee, been reappointed by the Association one of its research scholars for one year. The following additional grants have been made by the Council in accordance with the recommendation of the Scientific Grants Committee: Mr. Hankin £50 to continue his investigations into the nature of an albumose that has been obtained from anthrax cultures under certain conditions; Dr. R. Kirk £10 for a research on alcaptonuria and on the distinction between albumen and mucin in the urine, and some other points in connection with proteids in that fluid; Dr. J. R. Bradford £15 for some experiments on the action of the cortex cerebri on the vaso-motor system; Dr. H. H. Ashdown £10 for a continued research upon absorption from the bladder.

## TOPICS OF THE WEEK.

## THE ANATOMY OF THE FUTURE.

Some years ago an elderly professor of anatomy expressed his thankfulness that in the branch he taught there was no harassing progress. Physiology and chemistry, he said, were undergoing changes from one day to another, but anatomy was always anatomy, a bone was always a bone, and there was no wearisome struggle to keep up with the rushing progress of the times. And such is the view of anatomy entertained by many of the profession. Not a few of us think, when we look back over a number of years spent in active practice, that we started on our journey with much more baggage than was necessary in the way of memorized anatomical truths; that we could have done with a smaller quantity, but that that smaller quantity should have been better selected. We question whether the anatomy taught in our colleges to-day is the anatomy of the future. Is it not rather a result of the labor of successive generations of book-writers, each showing more eagerness to add new facts to the mass than to examine into and verify the old ones?

The anatomy of the future will not resemble that taught now. The scope of the subject requires enlarging, and for the narrowing memory work done to-day a broad view of the whole must be substituted. In other words, the student should first acquire a knowledge of general and comparative anatomy, and subsequently study its application to the human body. To begin work with the descriptive anatomy of man is working backward. Such a course has been likened to the study of an ultimate twig of a tree by a person who is ignorant of the character of the larger branches, of the trunk, and of the soil on which the tree grew.

Embryology urgently demands attention as a necessary introduction to the study of the parts of the body and as a subject the knowledge of which is of direct practical advantage in daily professional life. Observe how important has become the anatomy of the embryo in connection with the study of disease. The disposition of the layers of the embryo must be clearly understood to enable one to understand the structures of the body and the diseases developing in those structures. Studies such as these lighten the student's task. Take, for instance, the arrangement of the great vessels in the root of the neck. The disposition of these structures is learned commonly by the study of a scheme or diagram, perhaps by the friendly aid of a cunningly devised "tip." The relations of these vessels could, by the study of development, be so impressed upon the student's mind as never to be forgotten. Can any of our readers forget what a bugbear the peritoneum was? Can you put your hands on your hearts and say that you thoroughly understand all about it now? And yet, when the peritoneum is studied from its early and simple state there will be no longer any difficulty either in comprehending or remembering the arrangement of its folds.

The very great advance made of late years in the study of nervous diseases renders a change in anatomical teach-

ing very necessary. In our day the anatomy of the arteries was paramount, and the nervous system occupied a position of secondary importance. Yet the nerves, their cutaneous distribution, their communications with central ganglia and with one another, are matters of daily, almost hourly, consideration in the round of a doctor's visits, while of the arteries, over which we spent such time and such labor, there is rarely occasion to think. The practitioner is constantly meeting with nervous manifestations the correct interpretation of which renders a clear knowledge of nerve distribution necessary, while it is possible for him to practice for the whole course of his natural existence without ever being called upon to tie an artery. Should such a demand be made, he will seize the bleeding point in the wound, secure it, save his patient, and then go home to study the vascular system afterward. The statement has been made, we think by the late Dr. Fothergill, that the chances of an ordinary practitioner being called upon to tie the subclavian are almost equal to those of his meeting his death by lightning stroke.

To render the study of anatomy attractive and at the same time thoroughly useful, a complete change in our present system is called for, and teachers will soon have to consider the importance of comparative anatomy and of embryology as introductory studies, and the necessity of putting the nervous system in its proper place as the most important department of the human body, and not waste their energies in teaching the relations of arteries with which the student is unlikely ever to have anything to do.—Editorial—*N. Y. Med. Jour.*

## THE PULSE IN DISEASE.

While the clinician is accustomed to feel the pulse of his patient in order to add to his knowledge concerning the case before him, we think that he rarely does so because he expects to gain more than a general idea of the state of the circulatory apparatus, and with no attempt on his part to go deeper and determine the causes which produce the changes which he is so apt to note in his daily life.

We have already called attention in an earlier number of the Magazine to the stimulating influence which heat exercises in moderate amount upon the heart and its nervous ganglia, and have shown how the rapid pulse of fever is due to a stimulation of the cardiac accelerator nerves. We are accustomed to regard a rapid pulse as a concomitant of fever and to do no more, forgetting how the sudden fall of a high temperature may be followed by a cardiac failure, not due, as some have supposed, to exhaustion, but to the withdrawal of the accustomed stimulation. From the studies of Bruuton and others, we may have seen this fundamental fact concerning the pulse proved by the most positive experimentation.

The causes of collapse in the course of an acute disease such as scarlet fever, for example, are not so largely due to general exhaustion as we suppose. It is a matter of common-stock knowledge that excessive stimulation of any portion of the body means exhaustion. In a fever the high-bounding pulse of the early stages denotes not only an increased action of the heart, but also an in-

crease in the blood-pressure, from the excitement of the vaso-motor centre in the medulla. Under these circumstances the high fever suddenly drops, producing collapse, or, the fever continuing, a palsy ensues from excessive action. Such a result does not evidence nervous failure, but circulatory break down. Similarly the soft, compressible pulse of the person whose muscles are relaxed and flabby, evidences general lack of tone.

We have the several causes of rapid pulse. Fever, by its heat, exhaustion of the vagus, imperfect cardiac action, by which the tissues are strained and call for more blood, and finally relaxation of the blood-paths, whereby the resistance to the heart is decreased, and the heart rushes on unhindered and pumping into a huge expanse of blood-vessels.

The causes of the slowing of the pulse are equally numerous. The diminuation of pulse-rate by cold so seldom influence the heart in daily life as to be an unknown factor, but the vagal irritation and high arterial pressure are constantly at work, and it is often the part of the physician to relieve the spasm of the blood-vessels rather than to give stimulants to support the heart. By remembering facts such as these, we are often able to treat diseased states with not only a better appreciation of the requirements of the patient, but also with a clear understanding of the reasons for each and every change of treatment.—*University Med. Magazine.*

#### THE SPECULUM IN ANCIENT SURGERY.

DR. ALI COHEN, of Gröningen, describes, in the *Nederland Tidschrift van Geneeskunde*, a remarkable passage in the Talmudic treatise called the Niddah. The physician is there instructed, when it is uncertain whether hæmorrhage proceeds from the vagina or the uterus, to introduce a "siphopheroth" into which a "mechl" is introduced bearing "mouch." When the "mouch" is found, on retraction, to be covered with blood, that shows, according to the Niddah, that the hæmorrhage is uterine. It is expressly stated that the apparatus does not wound the patient in any way. The "siphopheroth" was a cone of lead; its orifice was bent inwards, so as not to wound the vagina. The term is manifestly corrupted from the Greek. The "mechl" was a long wooden rod, and "mouch" signifies a preparation very like charpie. Thus the mechl and mouch were the equivalents of the speculum forceps and wool. The siphopheroth was not the strict homologue of the speculum, but rather a contrivance meant to guard against a source of fallacy respecting the seat of hæmorrhage in pelvic disease. It is not stated that the instrument was designed for direct inspection of the cervix. Facts of this kind, unearthed by Dr. Cohen, are of considerable interest. They show that the sound scientific methods and ideas which prevailed in the old civilization of the Mediterranean basin were not confined to the Egyptians, Chaldees, and Græco-Roman nationalities, but also certainly flourished in Judea. Historians are fond of tracing the arrest of true scientific research, so marked in the Middle Ages, to the blending of Græco-Roman and Semitic ideas, so favorable to humanity in other respects. That very blending brought about more than one enlightened and

philanthropic religious system. Logically, it should have aided science. But science remained in abeyance till the Renaissance. The fault probably lay not in Christian and Jewish systems of civilization, but in the intellect of the Teutonic and Latin nations, which was insufficiently developed during the Middle ages to appreciate science.—*Brit. Med. Journal.*

#### THE GRAPHIC ARTS IN MEDICINE.

On Friday, November 1st, a meeting was held in the large theater of the medical school of St. George's Hospital, with Sir Prescott Hewett in the chair, to inaugurate a society for the encouragement of the pictorial and allied arts amongst past and present students of the hospital. In opening the meeting the Chairman expressed his opinion of the extreme value of drawing and painting to the medical man, not only for the actual results produced, but also, if seriously followed, on account of the value of the training. He then related how his pre-medical career had been passed in a French studio, and how the training had developed his accuracy of sight, and of what great importance this had been to him in his surgical work. Referring to photography, he mentioned that its importance was becoming daily more and more recognized, both in clinical and museum work, and reminded his hearers that modern photography owed its recent great progress to the enthusiasm of amateurs. Dr. Dickinson formally moved: "That a society be formed in connection with St. George's Hospital for the purpose of encouraging sketching, painting, engraving, modeling, carving, photography, and the arts of representation in general." One of the ways in which it was proposed to attain this end was to hold a meeting of the society at least once a year, at which members should exhibit any of their productions that could be included under the above headings. The meeting closed, after the election of officers and council, with a very cordial vote of thanks to Sir Prescott Hewett for taking the chair, and the society is fortunate to have secured him as its first President. Past students of St. George's who may be desirous of joining the society are requested to send their names to Dr. Penrose, the Honorary Secretary, at the hospital.—*British Medical Journal.*

#### VIRCHOW AND THE DARWINIAN THEORY.

According to the Vienna correspondent of the *British Medical Journal*, in Professor Virchow's presidential address at the recent meeting of the Anthropological Congress, the Darwinian theory was referred to, and he said that the intermediate link that should bring man and the ape into connection—the proper "prosanthropos"—had been sought for in vain. It was impossible even to determine the descent of single races from others; and it could be asserted that among the ancient races there was none that stood in any nearer relationship to the ape than ourselves. There was no tribe of people in the world that we were unacquainted with; and not one of the known tribes could justly be considered ape-like, appearances common to apes—such as prominences of the skull—being insufficient evidence of relationship. There was evidence that in the course of 5,000 years no remarkable changes of type had taken place. This adds to the evidence of the impossibility of the chasm between the highest type of anthropoid ape and the lowest type of man.—*New York Medical Journal.*

## PRACTICAL NOTES.

## BACTERIA IN WATER.

Water may appear clear, yet swarm with bacteria, nor does freezing much lessen the danger of water, since many bacteria are unaffected by freezing. Ice sometimes contains the bacteria of typhoid fever, indeed it may be nothing short of a congealed emulsion of bacteria with which we can inoculate ourselves. The protection of water from pollution by sewage is a problem which concerns everybody. Absolute safety can only be obtained by the use of ice artificially frozen.—Dr. C. G. Jackson.

## THE TREATMENT OF ECZEMA.

DR. UNNA, of Hamburg, publishes in the *Monat. für Derm.*, a paper on the Diagnosis, Etiology, and Treatment of Eczema. He says that even before the experimental cultivation of bacilli exact clinical observation had distinguished a number of entirely different types of eczema, and he thinks that each different type will be found to require a different mode of treatment. The type most frequently seen in Hamburg is seborrhœic eczema, and the parasite causing it is the same which in the first instant produces pityriasis capitis. Those persons who suffer from seborrhœic eczema of the head, including those affected with pityriasis capitis, are apt to suffer from the same kind of eczema on other parts of the skin. Dr. Unna has repeatedly pointed out that we possess a series of valuable remedies for the treatment of seborrhœic eczema in all its forms—viz., sulphur, resorcin, chrysarobin, and pyrogallol. Of these remedies resorcin is the best, as being the least likely to produce local or general ill effects. It may also be used in an alcoholic or watery solution, or in the form of ointment, paste, soap or powder. Dr. Unna's favorite formula is a solution of three drachms of finely-powdered resorcin with an equal quantity of glycerine in 6 ounces of spirits of wine, diluted with four times the quantity of water or chamomile tea. A thin layer of cotton wool well moistened with the solution is applied, covered with some waterproof material, and fastened by a bandage. These applications are particularly useful when the treatment is prolonged, or when it is carried out by night. They are, of course, impossible in general eczema of adults, but not in that of infants. Dr. Unna describes an especially important effect following the application of resorcin, viz., a swelling of the epidermis, by which all painful fissures are healed in a single night. In order to insure healing, he advises that the skin should be anointed after the removal of the bandage, and that washing with soap should be avoided. A few people suffer from a resorcin idiosyncrasy; this is, however, very rare, as he

has only met with it ten times in five years' observation, during which time he has seen 2,000 cases. He remarks that his treatment is not adapted to those cases of long-existing eczema in which strongly infiltrated or thickly-indurated patches occur.—*Lancet*.

## IODOFORM GAUZE IN POST-PARTUM HÆMORRHAGE.

DR. O. PIERING, assistant in Prof. Schauta's obstetric clinic in Prague, has published his experience in the employment of Dührssen's plan of plugging the uterus with iodoform gauze for post-partum hæmorrhage due to an atonic condition of the organ. Dührssen recommends that, when post-partum hæmorrhage comes on, the bladder should be emptied, and forcible friction and intra-uterine irrigation of hot or cold water, along with ergotinin hypodermic injections employed; that if the hæmorrhage still continues, the cavity of the uterus should be filled with iodoform gauze, the irritation produced by this setting up active and permanent contraction. The method has, according to Dührssen, the advantages of great certainty, complete harmlessness, and facility in its performance. Olshausen, Veit, and Tehling, however, say that the contraction set up is not always permanent, and that the method is not so free from danger as Dührssen believes. In consequence of these conflicting views, Dr. Piering resolved to give the method a trial, and he details several cases in which he employed it with complete success. In no case was any harm done by it. He advises that resort to the plug should not be too long delayed, and he prophesies an important future for the plug of iodoform gauze in post-partum hæmorrhage.—*Lancet*.

## COOLING OF THE BODY BY SPRAY.

DR. S. PLACZEK, following up some laboratory experiments by Preyer and Flashaar, on the effect of spraying a considerable part of the body surface of animals with cold water, has applied the spray for the purpose of reducing febrile temperatures in human beings. In the case of a man suffering from phthisis, whose temperature was high, he found that by spraying about a pint of water at between 60° and 70° F. over his body the temperature fell to normal, and continued so for several hours. Again, a similar method was satisfactorily applied in the case of a girl with diphtheria. In the healthy human subject the spray lowered the temperature nearly 2°, and in animals which had been put into a condition of septic pyrexia by injections of bacteria the temperature was reduced to normal by the spray. By keeping healthy guinea-pigs and rabbits some hours under spray and using from half a pint to a pint of water at the temperature of the room—44° to 62°—the temperature of the animals fell several degrees.—*Lancet*.

## SOCIETY PROCEEDINGS.

## The American Academy of Medicine.

*Thirteenth Annual Meeting, held at the Leland Hotel, Chicago, on Wednesday and Thursday, November 13 and 14, 1889.*

DR. LEARTUS CONNOR, OF DETROIT, IN THE CHAIR.

The officers for the year 1888-9 were the following:

President—Dr. Leartus Connor, Detroit, Mich. Vice-Presidents—Drs. Peter D. Keyser, Philadelphia, Pa.; L. Duncan Bulkley, New York, N. Y.; Theophilus Parvin, Philadelphia, Pa.; George J. Fisher, Sing Sing, N. Y. Secretary and Treasurer—Dr. Richard J. Dunglison, Philadelphia, Pa. Assistant Secretary—Dr. Chas. McIntire, Jr., Easton, Pa. Council—Drs. Traill Green, Easton, Pa.; Lewis H. Steiner, Baltimore, Md.; Henry O. Marcy, Boston, Mass.; Benjamin Lee, Philadelphia, Pa.; Albert L. Gihon, U. S. Navy; R. S. Sutton, Pittsburgh, Pa.; Lewis P. Bush, Wilmington, Del.; Frederic H. Gerrish, Portland, Me.; Leartus Connor, Detroit, Mich.; Peter D. Keyser, Philadelphia, Pa.; L. Duncan Bulkley, New York, N. Y.; Theophilus Parvin, Philadelphia, Pa.; George J. Fisher, Sing Sing, N. Y.; Richard J. Dunglison, Philadelphia, Pa.; Charles McIntire, Jr., Easton, Pa.; Hosmer A. Johnson, Chicago, Ill.; Gershom H. Hill, Independence, Ia.; Justin E. Emerson, Detroit, Mich.

## FIRST DAY.

After the reading of the minutes of the last annual meeting, and a verbal report of the Council, the Academy proceeded to elect a large number of Fellows, each applicant for admission having been endorsed by a Fellow of the Academy.

THE PRESIDENT appointed the following Committee on Nominations: Drs. Traill Green, G. H. Hill, and Alonzo Garcelon.

The following Reports were read from standing committees: Report of Committee on the Requirements for Preliminary Education in the various Medical Colleges of the United States and Canada. By Dr. J. E. Emerson, Chairman.

Report on Laws Regulating the Practice of Medicine. By Dr. Richard J. Dunglison, Secretary of the Academy.

This comprehensive report was chiefly the outcome of an extensive correspondence with gentlemen in the various States and Territories of the United States and in Canada who were directly interested in the subject, officially or otherwise, and whose names had been suggested to him by the distinguished Secretary of the Illinois State Board of Health. It gave, therefore, a very accurate and interesting view of the working of such laws in the regions indicated. It alluded to

the action of the Committee on Uniform Medical Legislation in the United States; of the American Medical Association at its late meeting at Newport; to the recent legislation in New York State, by which a certain standard of preliminary education was required of all medical students; and to the detailed operations of the law in about twenty of the States of this country.

In Kentucky, the law was generally observed, as it is in North Carolina. In Florida the law has the great defect of requiring every applicant to produce a diploma from a recognized medical college, and all those previously in practice one from a medical college *recognized by the American Medical Association*; but the latter has no relation to medical colleges, its membership being made up from medical societies only. The Virginia law is effectively carried out by the State Board of Medical Examiners, but the work of the Board has not caused the colleges to turn out any better graduates. The law is operative in Indiana; Maine is without any law, the one passed last year having been vetoed by the Governor; and the effect of the law is salutary in Missouri. The practical effect of the law has not been satisfactory to the State Board until recently the latter was strengthened by a decision of the Supreme Court.

In South Carolina the law has been slightly amended to increase its efficiency. In Wisconsin there is really no law which restricts the right to practice, although only graduates in medicine or those connected with organized medical societies can testify in court or collect fees by law. The law is efficient in Minnesota, and it is found that the applicants improve in general ability, intelligence and knowledge of medicine with each session of the Board. The law in that State is considered a great protection to the community, and has been strengthened by decisions of the courts. Texas is making strong efforts to secure a good law. The Tennessee law is not perfect, but is a decided improvement on the nothing which existed before it was passed. There is a good law in Maryland, based on the Illinois Act, but it is not practically enforced. The West Virginia law is working well, and that of Alabama is regarded by the profession in that State as "almost ideally perfect." In Arkansas there are numerous County Boards, but these, being appointed by County Judges, are often totally incapacitated for the duty.

In regard to the registration law in force in Pennsylvania, a correspondent expresses the view that it is the worst one of all, as the system of protection is applied for the benefit of the medical colleges, these being made the executors of the law, the Faculty of one medical college being made the absolute judge, without appeal, of the qualifications of the graduates of a competing medical college. He thinks unrestricted freedom is better for the public and the profession than an unfair law unjustly administered.

Reports were made from the following special committees:

Committee on Papers for Annual Meeting, Dr. N. S. Davis, Jr., Chairman.

Committee on Eligible Fellows, Dr. S. J. Jones, Chairman.

Committee on Publication of Transactions, Dr. A. L. Gihon, Chairman.

Committee on Preparation of a Catalogue of the Fellows, Dr. R. J. Dunglison, Secretary of the Academy.

Committee on Amendments to the Constitution, Dr. B. Lee, Chairman.

The following papers were then read:

*The Institutes of Medicine; the Necessity of their being Taught in our Schools*, by Dr. Cheston Morris, Philadelphia.

*Gymnastic Medicine*, by Dr. E. Hitchcock, Jr., Ithaca, N. Y. This paper was an interesting sketch of the influence of gymnastic treatment of disease, in place of that of mere drugs, and the writer's experience as Professor in Cornell University was cited in advocacy of the sound practical views entertained by him on the subject.

The Academy then adjourned until 3 o'clock P.M., when, Dr. Traill Green, being called to the Chair, the PRESIDENT, DR. CONNOR, delivered his Address on

THE AMERICAN ACADEMY OF MEDICINE, ITS SIGNS OF PROMISE AND OBSTACLES, ITS FIELD OF LABOR, AND SOME SUGGESTIONS LOOKING TO AN INCREASE OF ITS EFFICIENCY.

The paper is one that commends itself to every friend of liberal education and deserves what it will doubtless obtain—the general attention of the medical profession. Dr. Connor alluded to the fact that this was the first meeting of the Academy in the West. The idea that the Academy was founded upon a new idea born of an aristocratic modern notion was combated, the facts being that Hippocrates urged that the preliminary training of medical men be made as broad and deep as possible, while by precept and example the same idea has been maintained by all the famous medical men from Hippocrates to Alonzo Clark. The effects of such changes as are desired by the Academy are shown by what was accomplished by the Harvard Medical School when in 1870 it raised its standard of preliminary requirements; previous to this time the medical students were inferior to those of the other departments—now they are indistinguishable. It is objected by some that broad education does not pay. To this it is replied that the pure tradesman has no place in the temple of medicine; that the highest honors and emoluments during all time have come to the physicians who have sought to uplift the profession. The Academy is pleased to observe that

the effort made by the College of Physicians and Surgeons in New York and by other colleges to advance the requirements of preliminary education have yielded most satisfactory results; that a recent enactment by the State of New York shows that the principles advocated by the Academy have been adopted by a great commonwealth; that the enemies of the Illinois State Board of Health have failed to accomplish its ruin; that most encouraging results have been obtained by the efforts of the Minnesota State Board of Examiners, as evidenced by a recent enactment of the Minnesota Legislature; that similar progress has been made in Montana, Virginia and North Carolina; that earnest efforts in the direction of educational advancement are being made by the American Medical Association and by pharmaceutical societies.

Among the obstacles opposed to the adoption of the Academy's designs there is one indicated by the fact that the proportion of literary college students to the entire population has notably decreased. The medical colleges themselves oppose efforts to advance medical education. The professors of medical colleges are often inefficiently educated and hence do not encourage liberality of education in their pupils. The lukewarmness of many members of the Academy is opposed to the effective prosecution of its work. The greatest of all the obstacles to be encountered lies in the extensive general ignorance in the profession itself.

This part of the paper bristled with important and even startling facts illustrated by the citation of many important statistical figures. Among these may be noted the fact that among 9,306 medical students only 811 were possessed of literary degrees, of which number one-third emanated from institutions not recognized by this Academy.

Contrasted with veterinary colleges the comparison remains greatly in favor of the latter. The number of A.B.'s. in the medical profession is diminishing. On the other hand, the proportion of A.B.'s. in the various schools of medical practice presents a pleasanter picture, there being 94 per cent. among regulars and 6 per cent. among the various classes of irregular practitioners.

After a survey of the field of useful activity presented to the Academy, with various recommendations of plans for adoption, the paper closed with the necrological reports for the year. The recommendations were referred to the Council, with the thanks of the Academy for his able address.

The following papers were then read and referred to the Council:

*The Need and Position and Object of the American Academy of Medicine*, by Dr. Traill Green, of Easton, Pa., was read by title.

DR. S. J. JONES of Chicago, then read a paper entitled

# WHAT IS THE PROPER FUNCTION OF AMERICAN MEDICAL COLLEGES OF THE PRESENT TIME?

He gave a very entertaining sketch of the history of medicine, and particularly medical education, in this country from the earliest times. In Europe, he said, the requirements and attainments of medical men vary from time to time in the various countries. In this country our political characteristics are such as to acquire certain peculiar features in our medical institutions. For thirteen years the Academy has labored to increase the standard of preliminary education. It also aims to assist the student in the progress of his educational studies. The apprentice system in medicine, as well as its "office student" outgrowth, has been abandoned. The student does best to begin his medical education at the college doors, without seeking to prepare for his course by office reading with a so-called preceptor. Since the Academy first began its labors many changes have been inaugurated by the medical schools in order to suit themselves and the requirements and spirit of the times. The more advanced portion of the medical course is the one which has manifested the most improvement. The writer believes that the function of medical schools should be restricted to teaching, leaving the matter of examining and licensing to the various States, because of the variations in the requirements of medical practice in the different sections of the country. The mixed Board of Health, as seen in Illinois, has accomplished much good work.

There is nothing new in the idea of separating teaching from licensing in this country, for such a separation was seen even in the last century; while in New York, in 1839, the State Medical Society resolved that such separation was advisable. The question is asked, "Is such a separation practicable?" There were formerly objections to such a procedure, but these objections are no longer valid. The National Government does not assume the right to do this, but the power is conceded to the several States.

In the early record of American medical history it is interesting to observe that Drs. Rush and Drake were both bound out at a very early age as medical apprentices. This apprentice system ended at about 1810. The history of American medical colleges was traced from the foundation of the first in 1750 down to the present day.

The trouble with our modern colleges is that their facilities are too few and their numbers too great. It would be unfair to restrain a college from teaching because its facilities were not of the best, and yet at the same time a college diploma is an uncertain quantity and often very deceptive. As matters now are, in most States the authorities are obliged to treat all diplomas as though they knew them to be of a high order of value.

DR. HENRY M. LYMAN, of Chicago, then addressed the meeting on the subject of

## INSTRUCTION BY RECITATION.

He said that during the past eighteen years he had experimented in the methods of instructing medical students in the several departments of chemistry, physiology, nervous and mental diseases, and the practice of medicine. As the result of his experience, he believed it desirable to have recitation assignments of lessons made. Regarding the difficulties in the way of the practical application of this method of instruction, he found that the range of usefulness of this method is not so wide as in literary colleges. The topics best adapted to this form of instruction are the elementary branches, anatomy, physiology, chemistry and materia medica. Recitations should be combined with all necessary didactic exhibitions. In the advanced branches the conditions are different; here the student can still get the theories from the books, but it is his desire to learn the views of his various teachers. Recitation, however, may still be used to some extent even in the advanced branches. Tutors and tutorships should be established so that classes may be made small.

There are several difficulties in the way of the recitative method; first, there is the lack of suitable text-books. Some are too long, some too short, some not well balanced. There is a splendid field for writers in supplying this deficiency in medical literature. The second difficulty is to get well-qualified men to teach by this method. It is not easy to obtain tutors who are willing to work on the necessarily small salaries which have to be paid. It is not uncommon for students to request lectures instead of recitations, but at the end of a fair trial of the recitative method the students are generally well satisfied. One of the disadvantages in lecturing to large classes is that it is a very difficult matter to fix the attention of the students, who are apt to be distracted by the least break in the continuity of a lecture.

DR. J. C. MORRIS, of Philadelphia, said that the plan advocated by Dr. Lyman had been in operation in Philadelphia ever since he could remember—for the quiz classes are recitative classes. By this method he, as a quiz master, had taught chemistry, materia medica, physiology, and the practice of medicine. The better students all attended these classes, the method of teaching being something like that employed by the *privat doctores* of Germany and the tutors of Edinburgh. He said that the apprentice system in medicine gave way to the preceptor system, in which the teacher is expected to give instruction by the method of recitation. Teaching of this kind is highly necessary as a means of eliminating from the student's mind errors obtained from a failure to properly comprehend lectures, and as a means

also of increasing his information. In his experience as quiz master the examinations were more rigid than the general examinations, and very few students who were recommended by the quiz masters failed in their examinations. He would go farther than Dr. Lyman, and apply the method to all the branches of medical instruction.

DR. S. J. JONES said that the only difference concerned the method employed. The question is whether this form of instruction shall be imparted by the college itself or whether the matter be collateral and voluntary on the part of the student. As regards the year of preliminary instruction under a preceptor, it may be said to be of little avail to the student, who will generally accomplish quite as much by beginning his education at the college doors. The practical driller in college is as valuable as the Professor himself.

DR. P. J. FARNWORTH, of Clinton, Iowa, said that American students were adapted to this method of instruction. As lectures are arranged there is no time left for the students to read. The recitation method is in accord with the genius of our general plan of education.

DR. G. H. HILL, of Independence, Iowa, said that recitations would not be so necessary if students were A. B's. There are few students who know how to take notes.

DR. H. A. JOHNSON, of Chicago, said that the teacher comes too little into personal contact with the pupil. The recitation method is very helpful. In his teaching he has always made this his endeavor. Class quizzing is only useful when the attention of all is held. It is easier for the medical teacher to cram for a lecturer and talk for an hour than to hold recitations, for in this he has the floor and the students cannot talk back.

DR. LESTER CURTIS, of Chicago, described the most interesting lecture he ever heard. It was a kind of clinical quiz in which the patient's history was read, after which the pupil was given time for examining the case and prepare for his quiz, the teacher's function being mainly to keep him on the track. The interest manifested on the part of the class was almost dramatic in its intensity. Didactics have largely been abandoned on the continent.

DR. E. WING, of Chicago, found the theory of Colleges wrong, the fact being that students are not equipped with mental discipline. The quiz master and demonstrator knows best the student's condition and needs. Didactics are largely failures. In New York the lecture-rooms are deserted for the quiz-room.

DR. J. N. HYDE, of Chicago, found that the average medical student is taught according to better methods in this country than abroad. He found fault with the literary colleges for making a good literary education a luxury for the wealthy, whereby the medical student is largely debarred from a good foundation for his medical studies. This was not the case some years ago.

DR. A. GARCELON, of Lewiston, Maine, dwell on the importance of preliminary examinations. As for the recitation method of instruction this was in vogue where he began his medical studies fifty-three years ago.

DR. J. H. RAUCH, of Springfield, Ill., read a paper on

#### THE WORK OF THE ILLINOIS ARMY MEDICAL EXAMINING BOARD.

He said the Board was granted large discretionary powers and received the cordial coöperation of Gov. Yates. The Board's examinations were stringent ones, but they often found that men without diplomas were better qualified than men provided with them. The paper excited many interesting reminiscences.

DR. GREEN, of Easton, Pa., recited similar experiences to those of Dr. Rauch in his own Army experience. In examining homœopathists he generally found it useful to quiz on *materia medica*.

DR. S. J. JONES related some amusing experiences connected with his duties as examiner for the Navy.

DR. H. A. JOHNSON said that during his experience as an Army Examiner it often happened that his own pupils appeared for examination, when he sometimes found to his surprise that they had forgotten the points upon which he had placed most emphasis as a teacher. He explained this on the hypothesis that these were points of information that the practitioner had found little use for, and accordingly he was led to modify the character of his instruction. The late Dr. Flint had told him the longer he lived the fewer things he taught, but these things he made hooks upon which to hang important facts. The Army field was the best school of medicine ever afforded to the physicians of this country. It was a constant clinic.

#### SECOND DAY.

The Academy reconvened on Thursday morning at 10 o'clock.

DR. RAUCH, on invitation of the President, made some remarks on *The Advance of the Standard of the Medical Degree, as shown by the Statistics of the Illinois State Board of Health*.

The election of Fellows was then resumed, and nearly 100 in all, who had been approved by the Council, were elected.

The Secretary reported the action of the Council upon the report presented by the Committee on Amendments to the Constitution. Several of these amendments were reported negatively by the Council, in accordance with such report, and the following amendments, approved by the Council, were adopted by the Academy:

Paragraph 1, Section II, Article III, to read as follows: "The degree of Bachelor of Arts or of Master of Arts, after a systematic course of

study, preparatory and collegiate; but when a candidate has not received either of these degrees in course, other evidence of a preparatory liberal education which shall be considered as equivalent to the same by the Council (hereinafter to be provided for), may be accepted in lieu of a degree by the Academy."

Paragraph 3, Section II, Article III, to read as follows: "When a candidate is an alumnus of a foreign institution or institutions not granting the degree of Bachelor of Arts or Master of Arts, or of Doctor of Medicine, a certificate or certificates, or a license, which shall be considered as equivalent by the Council, may be accepted in lieu thereof by the Academy."

Article X, to read as follows: "A Latin certificate of fellowship, bearing the seal of the Academy and the signatures of the officers, shall be issued to any Fellow, on payment of its cost."

In consequence of the adverse report of Council, the other amendments were laid upon the table.

At the recommendation of Council, the following gentlemen were elected Honorary Members: Dr. David Jordan, President of the Illinois State University, Bloomington, and Sir James A. Grant, M.D., of Ottawa, Canada.

Several other gentlemen were elected Fellows of the Academy, having become eligible by reason of the adoption of the first-mentioned Amendment.

On motion, the recommendation of Council that the Academy should hold its next annual meeting November 12 and 13, 1890, in Philadelphia, was adopted.

The Committee on Publication of Transactions was continued, with approval of Council, under the same instructions as those given them at last annual meeting.

The President's Address was referred to the same committee.

On recommendation of Council, the other Special Committees were continued, the appointment of gentlemen composing them to be made by the incoming President.

The Treasurer's report was presented, and referred to a Committee of Audit, Drs. Hill, Heath and Garcelon, who subsequently reported the account as correct.

The Committee on Nominations reported that they recommended the following officers for the ensuing year: President, Dr. Samuel J. Jones, of Chicago, Ill.; Vice-Presidents, Drs. Justin E. Emerson, Detroit, Mich., Edward Hitchcock, Jr., Cornell University, Ithica, N. Y., J. Chester Morris, Philadelphia, Pa., Alonzo Garcelon, Lewiston, Me.; Secretary and Treasurer, Dr. Richard J. Dunglison, Philadelphia, Pa.; Assistant Secretary, Dr. Chas. McIntire, Jr., Easton, Pa.

After the election of additional Fellows, the reading of papers was resumed.

Dr. Gershom H. Hill, of Independence, Iowa,

read a paper on *The Moral Treatment of the Insane*, which was referred to the Council.

Dr. F. C. Heath, U. S. Marine-Hospital Service, read a paper on *Medical Harmony*, and Dr. N. S. Davis, Jr., one on *The Physiological Action of the Typhoid Fever Poison*, both of which were referred to the Council.

Other papers, the authors of which were not in attendance, were read by title, and referred to the Council: *The Need and Position and Object of the American Academy of Medicine*, by Dr. Traill Green, Easton, Pa.; *Aim and Scope of the American Academy of Medicine*, by Dr. Edward Jackson; *The Mission of the Academy*, by Dr. R. Lowry Sibbet, Carlisle, Pa.; *Brief Sketch of the late William Elmer*, late a Vice-President of the Academy, with appended resolution, by Dr. Lewis P. Bush, Wilmington, Del.

The following preamble and resolution, offered by Dr. Traill Green, were adopted:

The report of the good work accomplished by the Illinois State Board of Health having gone beyond this State throughout the United States, and received with approval, the American Academy of Medicine, in session in Chicago, congratulate the citizens of Illinois and the profession on the good which the Board has wrought by their action in securing an advance of preparation of those who minister to the people in their sickness.

*Therefore resolved*, That we approve the labors of the Board, whose action has been read by so many of our members in distant parts of our land; that the Fellows of this Academy testify to the influence of the Illinois State Board in advancing a better preliminary education for intending medical students, and a more extended course in the medical schools; and that they present to the Board their thanks for the help which the profession has received from their action, and wish for them continued success in their work and the support of their fellow citizens.

Dr. Jordan, President of the Illinois State University, then, by invitation, addressed the Academy on the changes that had taken place in the under-graduate courses.

The newly-elected President, Dr. S. J. Jones, was then inducted in the chair by Drs. Traill Green and H. A. Johnson, appointed by the President.

Thanks were tendered to the retiring President, Dr. Connor, for the able and faithful discharge of his duties; also to the proprietor of the Leland Hotel for courtesies extended.

The time of appointment of committees by the new President was, on motion, extended to be at the convenience of the latter.

The President appointed Drs. H. A. Johnson and G. H. Hill additional members of the Council for the ensuing year, and Drs. Emerson, Heath and McIntire the Committee on Eligible Fellows.

The Academy then adjourned.

THE grand duke Nicholas of Russia, who is suffering from cancer, has undergone a surgical operation for the introduction of a canula into the throat.

## DOMESTIC CORRESPONDENCE.

## LETTER FROM NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

*Academy of Medicine—A Plea for the Practical Utilization of Hydro-therapy.*

At the last regular meeting of the Academy of Medicine Dr. S. Baruch, who has for a number of years devoted much attention to the subject, read a paper entitled, "A Plea for the Practical Utilization of Hydro-therapy." He stated that this plea would be based upon historical, physiological and clinical grounds, and that it was his purpose to divorce the remedial use of water from its empirical union with hydropathy by urging its simplified employment by the general practitioner in his everyday rounds.

Having referred to the vast literature that had now accumulated on the subject, he gave a historical sketch of hydro-therapeutics from the time of Hippocrates, and then quoted from the writings of such modern clinical teachers as Niemeyer, Ziemssen, Dujardin-Beaumetz, Peter, F. A. Hoffmann and Semmola. The opinions of the most judicious, philosophical and successful physicians of past ages he went on to say, had been sustained by the judgment of the world's most enlightened era, and hydro-therapy had maintained its position not simply on clinical grounds, but was to-day more firmly established than ever, because it was based upon well-ascertained and exact physiological facts, the application of which formed the most brilliant chapters of clinical medicine. The works of Winternitz, Naumann, Chapman, Delmas, Bottey, Liebermeister and others teemed with experiments on animals and man, which must prove to the unbiased observer that by means of the thermic and mechanical effects of water prompt and decided modification may be impressed on all the functions of the body.

Having dwelt for some time on the physiological effects produced by water, as recorded by various observers, he quoted as follows from Dr. M. P. Jacobi: "Sleepiness during the pack nearly always occurs in successful cases, and we have found the greatest amount of benefit to accrue when the patient was able to sleep for half an hour after the completion of the pack and massage. If, during the first period of the pack, we may assume, for reasons already stated, that blood circulates in increased volume and under increased pressure through the nerve centres, and that, in consequence, the acid fatigue products, which had been maintaining a permanent excitement of nerve elements, could be completely removed, the immediately subsequent diminution of blood supply effected during the second part of the pack cannot fail to be a great advantage, for it lowers the functional activity of the nerve cen-

tres, that had been unduly prolonged, and brings them, therefore, into the condition which is a necessary preliminary to the beginning of nutritive assimilation. The diminution of the blood supply is not sufficient to interfere with this latter process, for it is not below the point which exists in sleep, the physiological period for nutritive assimilation in nervo-muscular tissues. Accepting Ranke's law for these tissues, that they are only nourished when fatigued, *i. e.*, relaxed, we may see, further, in the muscular relaxation induced by the warm moisture of the pack, a condition most favorable for the nutrition of muscles."

In entering upon the discussion of clinical evidence, Dr. Baruch remarked that, unfortunately, experience had been so often involved upon the subject by empirics that the profession had looked askance upon this argument. He said he agreed with the latest German author on therapeutics, F. A. Hoffmann, who states that he does not deal with the disease, but with the sick man, and who divides therapeutic methods into the direct, which acts by removing the cause, and the indirect, which by influencing the circulation and nutrition of one or more organs, or the general tissue changes, serves to remove the disease or make it recede. He would add a third method, viz: that by which we may so impress the various functions of the body (chiefly through the innervation which governs them all) as to enhance the resisting power of the patient, and thus enable him to escape the dangers which are known to be lethal. All these methods, he said he proposed to demonstrate, might be sought in the proper application of hydro-therapy, although he wished to be distinctly understood as not claiming this as an universal remedy, to the exclusion of drugs. The position in which he would place it was that of a valuable, indeed an indispensable, auxiliary to other treatment.

As he conceived it, hydro-therapy might be defined as the utilization of water at any temperature and in any form, from ice to vapor, internally or externally, for the treatment of disease. By such a definition it was emancipated from hydropathy, or the cold water cure, and placed clinically in the front rank of therapeutic measures. The modern discovery of the microbic origin of many diseases would, if verified by clinical experience, present a large field for therapeutic labor in this direction. Thus far less had been accomplished in this field than could be wished for; but in the gastric and intestinal diseases of infancy we seemed to be on the threshold of its fulfilment. Clinical study had demonstrated that many of these affections were due to toxic products derived from the microorganisms which had found their way into the alimentary canal, chiefly through milk food in summer; and to remove these, and reinstate the gastro-intestinal func-

tions, water had been used with great success. Intestinal irrigation carefully and thoroughly done with a large Nélaton catheter, with the patient on the abdomen, and by means of a fountain syringe holding not less than a quart of water, had proved the most efficient method of treating several types of summer diarrhoea, even after they had assumed a threatening phase.

Another hydropathic method, which acted by removing the cause of disturbance, was the sipping of hot water an hour before meals in dyspepsia. The hot water craze, which had now taken a firm hold upon the lay public, was but the legitimate outcome of a valuable therapeutic application of water whose simplicity commended it at once to the judgment of the intelligent physician. Brought into prominence by Dr. Saulsbury, who committed the error, so common among enthusiasts, of regarding his remedy as a panacea, it had become adopted by the profession as a most valuable agent in many gastric troubles, removing the products of fermentation, cleansing the mucous membrane, restoring tone and vigor to the gastric lining, and enabling the natural forces to come into play.

Having alluded to the successful management of ileus, as attested by Kussmaul and Senator, by irrigation of the stomach with large quantities of water, he spoke of the second method of treatment mentioned, viz: that which acts by affecting the nutrition and tissue changes. Among the affections amenable to this were neurasthenia and other nervous troubles, gout, rheumatism, obesity, scrofula, anæmia and chlorosis. For practical purposes in hydropathic management, he said, he divided neurasthenia into two types, the erethic and the true asthenic. The former, which was characterized by an irritability of the nerve forces, was most appropriately treated by soothing measures, such as cool ablation or prolonged wet packs, followed by the half bath at 65° to 70°, once or twice daily. The asthenic form, on the contrary, required the stimulus of the powerful reaction produced by the impingement of a mass of cold water for a brief period, and the effect was greatly enhanced by general faradization. Between these two extremes there were intermediate forms, to which the flexible procedures of hydrotherapy admirably adapted themselves.

Hysteria also presented a wide field for hydrotherapy. In his personal experience, he said, so many cases had yielded to the tonic influence of various hydropathic measures that he was firmly convinced of the extreme ability of this method of treatment. Here, too, he thought it was important to differentiate the types of the malady and adapt our procedures to each one with precision. In his private and hospital practice he now employed no other remedy in hysteria, and at the Montefiore Home for Chronic Invalids, where he was in attendance, three cases had re-

cently been discharged cured which had been admitted solely because they were believed to be entirely incurable. In chorea hydrotherapy had been found of the greatest possible service, although in this affection it was used as an adjunct to other treatment, and not as the exclusive therapeutic agent.

In various forms of neuralgia also it had won many triumphs, and in Dr. Baruch's hands sciatica has yielded more readily than other varieties. In the acute form the patient is wrapped in a dry woolen blanket and, after lifting the blanket, pieces of old blanketing, doubled and thoroughly wrung out of boiling water by means of a wringer, are closely applied to the affected limb over the region of the nerve. These are rapidly changed until the parts become thoroughly congested and the patient is bathed in perspiration, and this treatment is continued for about half an hour. The blanket is then removed successively from various parts of the body, beginning with the affected limb, and these are rapidly washed with water at 65° and dried. In chronic cases, in which the general health is impaired, the general tonic treatment by cold ablutions, douches or plunges is indicated.

In functional anæmia the tonic effect of hydrotherapy, he said, was especially pronounced, and for many years he had been in the habit of prescribing cold ablutions while the patient was still warm from the bed, as a prominent element in the treatment. In the early summer months, when the water was of a temperature of from 70° to 75° and the air not much warmer, the shock would be slight. Hence it was necessary to add ice to the water, or several basins might be precipitated over the shoulders and body from a height, in order to compensate, by the mechanical effect, for the absence of temperature difference. In winter his usual prescription was to stand in sufficient warm water to cover the feet, and, after turning the cold water on, to catch it up with the hand or a small pan and dash it over successive parts of the body, after which rapid drying and friction should follow. After the patient had become accustomed to the cold water he advised the plunge into a tub three-quarters full of water of not less than 55° nor more than 65°. Its duration, however, should not be longer than was required to wet the entire body. In diathetic diseases, such as gout and rheumatism, in which anæmia was present as a manifestation of deficient nutrition, excellent results might also be accomplished by the skillful adaptation of cold water to the case.

Having spoken in detail of the good effects of hydrotherapy in phthisis, chronic constipation and chronic gout and rheumatism, and given illustrative cases, he passed on to its use in febrile diseases, in which the third method of treatment referred to, viz: arming the patient for the battle

with disease, was illustrated. Statistics which were unimpeachable, he said, had demonstrated that the mortality from typhoid fever had been reduced from 25 per cent. to 2 per cent. by the systematic adoption of the Brandt method of cold bathing. In this connection, he said, he desired to reiterate the necessity of implicitly following an exact technique in hydro-therapy. Wrapping a typhoid fever patient in a sheet and sprinkling him with ice water, or sponging with cold water, could not be regarded as at all taking the place of cold bathing. The bath should be adapted to each case, and the fact should never be lost sight of that its object was not to reduce temperature, but to refresh the nervous system and enable the body to withstand the lethal influences at work in the regular process of the disease.

It ought perhaps to have been mentioned that three patients with phthisis treated by hydro-therapy, in addition to other remedial measures, at the Montefiore Home gained respectively 10, 11 and 17 pounds, while the symptoms of the disease became greatly ameliorated or disappeared altogether.

In the discussion which followed the paper Dr. George L. Peabody said that it was a matter of surprise to him that it should at the present time be necessary for Dr. Baruch to urge upon the profession the advisability of making use of cold baths in the febrile diseases. It seemed, however, that the old prejudice against this procedure had been revived and amplified, it being regarded by many as dangerous to suddenly alter the temperature of the medium with which the patient was surrounded. But so far from this being the case, it was a fact that it was almost impossible to give a patient cold who had a temperature much above the normal. We certainly ought not to be satisfied with the results at present obtained in typhoid fever. The proportion of deaths was from 20 to 30 per cent., and this was much higher than in many of the European hospitals, where cold bathing was regularly employed. Brandt's latest statistics of typhus and typhoid embraced nearly 6,000 well-authenticated cases in which his method was systematically practiced, and the percentage of mortality was only 3.9. Why was not this method generally adopted here? Because, as Prof. Horatio Wood had said, the medical profession had not yet risen above the existing prejudice against it. Another reason was because the method was troublesome and expensive, requiring a portable bath-tub and the services of two attendants. There was no question that the full bath, at a temperature of from 65° to 70°—68° being the best for the average class of cases—was much more beneficial than any other application of water; the bath being repeated sufficiently often to keep the body temperature at or below 102°.

Dr. A. A. Smith said that when he recently

succeeded Dr. Flint in the medical service of Bellevue Hospital there were four cases of typhoid in the wards which had been treated by the cold bath method with perfect success, and he had carried out the treatment as long as it was required. Since then, however, five cases had been admitted none of which seemed to him to justify the adoption of this procedure; and he thought, therefore, that a very large number of cases were required to base any results upon.

In answer to a question by Dr. M. P. Jacobi, as to whether he would employ the baths in a malignant case of typhoid with low temperature, Dr. Baruch said that he certainly would if the temperature was as high as 102°, although in a somewhat modified form. He would place a patient of this kind in a tub of warm water, and then employ short affusions of cold water over the shoulders.

## BOOK REVIEWS.

AN INTRODUCTION TO PATHOLOGY AND MORBID ANATOMY. By T. HENRY GREEN, M.D., PHYSICIAN TO CHARING CROSS HOSPITAL, ETC. SIXTH AMERICAN FROM THE SEVENTH ENGLISH EDITION. Revised and Enlarged by STANLEY BOYD, M.B. Lond., F.R.S. Eng.

The fact that in so short a period of time this work has run through seven editions in England, and six editions in America is ample evidence of its value and of its popularity. The practitioner and the student alike have found in it the latest and most reliable expressions of pathological research. While the former editions are too well known to require minute description, it should be stated with reference to this last, that it has been so far re-written, as to include the latest accepted views and the latest investigations in the several departments of pathological study. Thus the chapters on Inflammation, Fatty Degeneration, and Vegetable Parasites, have been essentially recast, and will, we think, be found accurate up to date.

The Genesis of Cells; the Etiology of Disease; the Arrest of Nutrition; the Various Forms of Degeneration; the whole subject of Tumors; Carcinomata; the Blood; Inflammation; Fevers and Infective Granulomata; Scrofula; Leprosy; Syphilis; Glanders; the Inflammation of Special Tissues; Septicæmia; Pyæmia and the Vegetable Parasites are the subjects of which it treats in a lucid and masterly manner.

The work containing over five hundred pages is well illustrated, and the publishers, Messrs Lea Brothers and Co., have produced it in the exceptionally fine style and finish characteristic of their publications. It contains a large amount of valuable instruction, such as every physician

needs, and it should have its place in every medical library.

For sale by A. C. McClurg & Co., 117, 119 Wabash Ave., Chicago. Price \$2.75.

A TEXT-BOOK OF HUMAN PHYSIOLOGY, including Histology and Microscopic Anatomy, with special reference to the Requirements of Practical Medicine. By DR. L. LANDOIS, Professor University of Greifswald, Third American, Translated from the Sixth German Edition, with Additions by WM. STIRLING, M.D., Sc.D., Professor of Physiology and Histology in Owens College, etc.

This great work of Dr. Landois is well known to the medical profession. Its successive editors in Europe and in this country have been rapidly exhausted, and special credit is due to Messrs. P. Blakiston, Son and Co., for the admirable manner in which they have now brought out the third American edition. It is idle to attempt in this brief review, any elaborate description of this valuable treatise. In its treatment of its various subjects, the work is exhaustive, and yet never tedious.

The approved methods of physiological investigation are so clearly expressed, and often so exquisitely illustrated that the student is able to follow the master through each and every demonstration.

Much as we have esteemed our own American Text-Books, it is with no disparagement to any that we assign for this work the foremost place in its methods of dealing with human physiology, histology and microscopical anatomy.

The work is published in the best style of the publishers, and its profuse illustrations are a credit to the engraver's art. It will be deservedly popular, and will render a valuable service to the American profession.

## MISCELLANY.

MEDICO-CHIRURGICAL FACULTY OF MARYLAND.—The semi-annual meeting of the Medical and Chirurgical Faculty of Maryland was held at Hagerstown on November 12 and 13. The address of welcome was delivered by Dr. A. S. Mason, of Hagerstown, followed by remarks by the President, Dr. A. Friedenwald, of Baltimore. Papers were read by Drs. J. J. Chisolm, Robert W. Johnson, Edwin Michael, George H. Rohé, William B. Canfield, Joseph T. Smith, Randolph Winslow, T. A. Ashby, S. T. Earle, William Lee, J. N. Mackenzie, and George J. Preston.

Hay, Philadelphia; The Cleveland Medical Gazette, Cleveland, O.; The Microscope, Trenton, N. J.; Dr. A. I. Thomas, Chicago; Dr. George W. Davis, Kansas City, Mo.; Dr. Chas. P. Knapp, Wyoming, Pa.; Dr. Frank Trester Smith, Chattanooga, Tenn.; Dr. C. H. A. Kleinschmidt, Washington; Dr. J. D. Couch, Somerville, Mass.; Dr. Joseph Eastman, Indianapolis, Ind.

### *Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from November 16, 1889, to November 22, 1889.*

By direction of the Secretary of War, the extension of leave of absence on surgeon's certificate of disability granted Major Leonard Y. Loring, Surgeon, in S. O. 241, October 16, 1889, from this office, is still further extended one month on surgeon's certificate of disability. Par. 3, S. O. 263, A. G. O., Hdqrs. of the Army, November 16, 1889.

Capt. Edward B. Moseley, Asst. Surgeon, is relieved from duty at Whipple Bks., Ariz., to take effect upon the expiration of his present leave of absence, and will report in person to the commanding officer, Ft. Clark, Tex., for duty at that station, reporting by letter to the commanding General Dept. of Texas. Par. 4, S. O. 268, A. G. O., November 16, 1889.

Capt. Walter W. R. Fisher, Asst. Surgeon, is relieved from duty at the Presidio of San Francisco, Cal., and will report in person to the commanding officer, Ft. Assiniboine, Mont., for duty at that station, reporting by letter to the commanding General, Dept. of Dakota. Par. 4, S. O. 268, A. G. O., Hdqrs. of the Army, November 16, 1889.

Capt. Rudolph G. Ebert, Asst. Surgeon, leave of absence on surgeon's certificate of disability granted in S. O. 109, May 11, 1889, from this office, is extended six months on surgeon's certificate of disability. Par. 13, S. O. 270, A. G. O., Hdqrs. of the Army, November 19, 1889.

### *Official List of Changes in the Medical Corps of the U. S. Navy for the Week Ending November 23, 1889.*

P. A. Surgeon W. H. Rush, ordered to U. S. S. "Saratoga."

Asst. Surgeon J. F. Urie, from coast survey Str. "Gedney" and to the U. S. S. "New Hampshire."

Asst. Surgeon P. H. Bryant, from the Norfolk Hospital and to the coast survey Str. "Gedney."

Asst. Surgeon Geo. T. Smith, from the Army and Navy Hospital, Hot Springs, Ark., and to Naval Hospital, Norfolk, Va.

Asst. Surgeon E. P. Stern, after examination for promotion await orders at Boston, Mass.

## ADDRESSES.

### THE AMERICAN ACADEMY OF MEDICINE;

#### OBSTACLES TO THE GENERAL ADOPTION OF THE PRINCIPLES OF THE ACADEMY.

*Address of the President delivered at the Annual Meeting in Chicago,  
Ills., Nov. 13, 1889.*

BY LEARTUS CONNOR, A.M., M.D.,

OF DETROIT, MICH.

(Concluded from page 762.)

We are compelled to admit the existence of another side of the picture. There are numerous serious obstacles to the rapid adoption by the medical colleges of a high grade of preliminary requirements from their students. Among these we note a few:

1. According to statistics collected by the late President Barnard, of Columbia College, it appears that, the proportion of literary college students has diminished during the past fifty years from 1 in 2,000 of the entire population to 1 in 2,500. During these fifty years the population has increased about fourfold; the number of colleges threefold, but the aggregate number of students in all the colleges but little more than twofold. The causes that have thus diminished absolutely the number of bachelors of arts we cannot discuss, but the fact exhibits one reason why more bachelors of arts are not found in the medical profession, and why a high degree of preliminary requirement is not generally regarded as necessary for entering upon the study of medicine. Significant of the continuance of this tendency of the age is the election of Ex-Mayor Low, of Brooklyn, N. Y., to the presidency of Columbia College. That a wealthy and successful business man, an able and astute politician with no practical training in the art of teaching, should be placed at the head of one of the most prominent literary colleges of the United States, is certainly a spectacle worthy of the most careful study. Has business so absorbed the best brain of the land, that from its ranks must be chosen the leaders of the intellectual and moral training of the country? If so, then we have to meet an obstacle of the first magnitude in the prosecution of our work. In any event we are a

part of that protest which every scholar must utter against any and every capitulation of intellectual and moral life to commercialism. At every turn we shall be opposed by the trade spirit of our country and our time. This trade spirit cripples the efforts of not a few members of this Academy. One of our distinguished members in his labors said that he was most discouraged by some of those having abilities refusing to attempt certain work because it would not aid in filling their offices with patients, and their pocket-books with dollars. Recognizing our foe, we shall not be surprised at his unexpected and unwelcome presence, but be ever prepared to do what we can to thwart his purposes.

2. It is an historic fact that the medical colleges have constituted a powerful obstacle to an increase of the preliminary requirements. The history of the profession of Ontario fully substantiates our proposition. The colleges there were finally compelled to yield, as at last they must in the United States. This action of the medical colleges is based upon the trade aspect of their work. Adequate preliminary education, if exacted by all colleges, would reduce the sum total of student's fees, and other perquisites. The exaction by one school having no other advantages than its rival, of a high admission examination, would send a portion of its students to its rival. So in a variety of ways the principles of the Academy antagonize the trade interests of the medical colleges. Hence we can understand the efforts they put forth to defeat the enactment of laws adequate for the certain enforcement of an honest efficient preliminary examination and rational college training. That which has been made public is probably only a tithe of the antagonism already existing. Dr. P. H. Millard in the report already referred to, says "that only those who by their official position have been compelled to enforce the medical Acts of Minnesota, Illinois, Missouri, West Virginia, etc., can appreciate the obstacles and intolerable embarrassments encountered in their execution. The most captious criticism and formidable opposition came from the profession itself. This criticism and opposition did not come from the narrow minded cynic alone, but to the shame and disgrace of the profession, from a large number

of our medical institutions, some of which, we regret to mention, were manned by men of eminence and great learning, but had carelessly for financial reasons, given cognizance to an opposition to a reform which was entitled to the undivided support and encouragement from every member of the profession from the Atlantic to the Pacific. Of the nine attempts, to repeal the present Minnesota Practice Acts, at the last session of the Legislature of Minnesota, a majority of the professed amendments emanated directly from the medical colleges themselves." The evidence is overwhelming of the open and covert opposition of the mass of medical colleges to all enactments tending to limit the numbers of their students, and among these must be classed a proper preliminary education. They love large classes better than small ones. Reforms that will benefit their individual interests they will adopt, all others must receive their condemnation.

Many years ago the speaker attempted to persuade a member of this Academy, known the world over for his great learning, splendid abilities and apparent devotion to the advancement of the medical profession, to exert his influence with his own college to establish a preliminary examination, and a three years' graded course. He listened to me patiently, and when my plea was finished, he said: "My dear doctor, I believe in the absolute truth of what you say. By no other means can medicine be properly taught. For more than two score years I have said to myself as I finished my course of lectures, 'another farce ended.'" But he said, placing his hand upon his pocket-book, "the real trouble lies just here. The doing as you suggest by my college would diminish its income and the salaries of its teachers. We cannot do it." He did not do it, nor has his college done it to this day. I suspect that it never will do it until it can be shown to pay in money.

Admitting this hostility of the majority of medical colleges to the principles of the Academy what can it do in the matter? Its collective wisdom can most wisely answer this question, but it would seem evident, that the members of the Academy could cast their influence with such colleges as honestly did enforce an adequate preliminary examination. It could also assist in the enactment of such State laws as will compel all colleges whose diplomas are recognized within its borders, to enforce proper preliminary training. In one or both of these ways it might finally be made profitable for the hostile colleges to join in the vigorous prosecution of our work.

3. It is unfortunate, for the cause of preliminary education, that so large a proportion of the professors in medical schools fail to possess the training needful for the acquisition of the degree of A. B. Not possessing this training they are unable to comprehend its value to their stu-

dents, and so are little likely to encourage them to obtain it. Naturally they oppose the requiring by their college of a higher general education than they individually possessed. They became professors, because of the fact that they had money or push to invest in the business enterprise, which was to enable the professors to distance all their competitors in the profession. Those who were not taken in gathered together of the remaining doctors in the town those having the most money, and push to the end that they might make as large an impression as their rivals, and so get as much or more business, and so make as much or more money, and so attain as extended a notoriety. It is beyond a question that most of American medical colleges originated in one of the two ways mentioned. From this origin it is clear that the general education of the professors was the least important item. Some were organized in other and less mercenary ways, others have outgrown the character with which they were born, so that there are medical colleges whose teachers are all that could be desired. Doubtless the remainder will be changed with the natural progress of events. It might be helpful in promoting this change if the exact number of bachelors of art among the professors could be ascertained and published to the profession and the laity. We cheerfully admit that many excellent practitioners and able teachers are found, among the professors of medical colleges, without the degree of bachelor of arts, men who have supplied by later studies the deficiencies of their youth. These are men of commanding abilities and indomitable energy who would have conquered all obstacles in any calling. But others in large number exist whose early defects have not been rectified in this manner, and whose presence in the lecture room of the college is an offence to any well educated, well bred person.

4. The lukewarmness of so many members of the Academy is another obstacle to the effective prosecution of our work. Those not members, notice and comment upon this state of things. They see members teaching in medical colleges which maintain no preliminary examination; they see members taking students under their direction who have the merest smattering of general knowledge; they observe at the yearly meetings of the Academy only two or three score members present; they rarely, if ever hear members speak of the Academy and comment upon it to the physicians about them; in all these respects they differ little, if at all, from non-members of the Academy. True, the Academy has ever had a remnant to whose faithful services it owes its continued existence. The remedy for this state of things is for each member to arise and enter upon his proper duties as a disciple and preacher of the doctrine of the advancement of general education in the medical profession.

5. Lastly, our greatest obstacle is the extensive general ignorance throughout the medical profession. I had collected verbatim letters illustrating the degree of this ignorance, but from lack of time I will not read them. Nor can I dwell upon the prevalence of this ignorance. It is everywhere apparent to the annoyance of the well educated. Medical editors, secretaries of medical societies, and all having large correspondence with the profession, tell the same story of the constant exhibition of a vast amount of actual illiteracy among members of the medical profession. It is a humiliating fact, that the medical journals having the largest circulation are those who cater to this illiteracy. An editor himself, a man of general and special culture, in response to my expression of wonder that he could have any connection with a medical journal of this class said: "I know well this element in the profession. It regards a really good medical journal as a 'kid glove' affair fit only for the 'aristocrats.'" They will not take, nor will they read such a journal. Hence, it is better to make a far inferior journal that they will take and read. This, he said, is the reason for the existence of those medical journals so offensive to the really intelligent practitioner. He then gave me the following picture of such subscribers as he had found them. "The typical doctor of this sort spends much of his time gossiping in the saloon or in the grocery. His office is as dirty and unkempt as himself. While there, his favorite posture is to sit in an old greasy chair with his feet upon an old dirty, dilapidated table. With an old pipe in his mouth he puffs and spits about his pen, removing his pipe only as necessary for conversation to his patient. When the mood takes him he writes to his medical journal. With lead pencil, and a piece of brown wrapping paper, he gives expression to his ideas, in language and forms quite unknown in classical English." All will admit that the presence of such men in the profession constitutes a formidable obstacle to the work of the Academy. To limit additions to their ranks is one of the ends sought by the Academy.

Since our last meeting the Academy has lost several of its members by their journeying to that country which persistently receives and never returns its visitors. Preëminent among these, was Dr. J. L. Cabel, for fifty-two years a teacher in the University of Virginia. During this entire period he was known as the typical gentleman of culture and refinement, the teacher of living medicine, able to inspire his pupils with that enthusiasm imperative for attaining the best results; the learned scholar who from time to time gave of his labor for the benefit of his fellows, freely, fully and without price; the professor whose councils aided in establishing and main-

taining a sound system of training for medical students, a system peculiar to the University of Virginia; a sanitarian high in the councils of his fellows; not to particularize further a man typical of the best development of his race. Like a ripe sheaf he was gathered to his fathers when his life had been fully rounded out. Last January I wrote, asking him to assume the duties of chairman of the committee on new members. I knew that his name would carry great weight among both old and young, in all groups of physicians in every portion of the land. Almost by return mail I received a long letter from him, explaining in detail that for some years he had been compelled to forego the pleasure of engaging in such work, though often solicited by gentlemen whom he specifically mentioned. He said that he wrote thus in detail lest the Academy might think that he desired to shirk any duty to the profession he loved so well, or to the Academy whose principles had been his life long standard. Had his physical condition admitted, he said this service to the Academy would have been performed with the greatest delight. As President of the Academy, I responded to this touching letter in terms such as would have sprung from the heart of any member. To this he replied on February 1, thus: "I have this moment received your very kind letter of the 29th ult., and I cannot resist the impulse to tell you how much gratified and touched I am by your generous expressions of sympathy and regard, not to speak of your too flattering estimate of the little work I have done with a view to the elevation of the standard of medical education, and to the furtherance of all enterprises looking to the improvement of our common profession."

Dr. Stephen Weeks, of Orange, N. J., one of the early members of the Academy, and Dr. William Elmer, of Brighton, N. J., have also passed to the unknown shores. The first was born in 1813, and the other in 1814. Both came of stock distinguished for its culture, and largely impregnated with the pursuit of medicine. Dr. Elmer was formerly a Vice-President of the Academy. We also note the deaths of Dr. Theodore I. Wing, of Susquehanna, Pa.; Dr. James Foultes, of Oakland, Cal.; Dr. James Kerr, of York, Pa., and Dr. J. I. Miner, of Wilkesbarre, Pa.

Our meetings are marked with two acts typical of human life. We record the admission into our ranks of members, and we note the passage of others from our ranks into the land of the majority. We remain between this advancing and retiring column in which narrow space we complete our work. In full view of these, let us ponder the problems before us, decide upon our line of action, and joyfully march to the conflict. As physicians, we are bound to cherish and keep bright the golden thread of professional truth, honor, and progress, which connects us with the

portion of our army already passed beyond our ken, that when we join it, a still brighter thread will be left to guide those following us. As men we will ever exhibit a manly independence and kindly affection toward all, so that when our turn comes to join the departed throng we shall do so with the consciousness that we have done what we could for the uplifting of our fellows and the ennobling of our race.

## ORIGINAL ARTICLES.

### INTESTINAL DISEASE OF CHILDREN DURING HOT WEATHER.

*Read in the Section of Diseases of Children, at the Fortieth Annual Meeting of the American Medical Association, June, 1889.*

BY PETER HOOPER, A.M., M.D.,

OF PHILADELPHIA, PA.

The causes of intestinal diseases in hot weather are mainly heat, impure air and improper food. Heat alone is evidently not the sole cause of intestinal diseases of children in hot weather, for relatively these diseases are more prevalent in the city than in the country. Still, heat is a potent factor, and I will consider this first.

The local abstraction of heat from the bodies of children suffering from entero-colitis or gastro-enteritis, I have always found to be productive of good. The use of cold water and cracked ice internally is also beneficial. Cold water compresses or the ice-bag applied to the head will reduce fever, and whenever I have used it there has been an improvement in the diarrhoea also. Since gastro-enteritis is chiefly a disease of hot weather, our object should be to lower the temperature, and this can be done by the keeping of large pieces of ice in the sick-room. The following case came under my care June 12, 1887:

H. S., aged 8 months. When I first called to see the child he had been sick for two weeks. Measles and gastro-enteritis was the history given to me on my first visit. I found the little patient in almost incessant convulsions, with rapid breathing, the pulse quick and jerking, the carotids strongly pulsating, the pupils contracted, the sphincters relaxed, and having very thin fecal evacuations. The temperature in the axilla registered  $109\frac{2}{3}^{\circ}$  F. The treatment was the immediate use of the cold pack. Ice was rubbed down the spine and a block of ice was placed under the neck. In half an hour the temperature had fallen to  $105^{\circ}$  F., nothing being given internally. I directed that, during my absence, the same treatment be continued whenever there was any rise in the temperature. Chronic entero-colitis of several weeks' duration followed. During this time I continued the use of ice and ice-cold water externally and internally, and calomel, pepsin, bromide, bismuth and quinine suppositories were given whenever they were indicated. The mother

kept the child out of doors in the cool air and shade a great deal of the time. This she was able to do by going to the old family homestead, which had shady grounds and an unobstructed exposure a great distance in front of the house.

The principal infant foods were badly digested, and no improvement was made until cow's milk was given, peptonized at first and afterwards pure, being obtained from a farm near by. In October of the same year, while the child was still under treatment, hip-joint disease developed, which was cured by deep massage and inunctions of lanoline. Chorea next developed and remains to this day. Excepting this disease the child is healthy and well nourished. In this case the free use of ice and ice-water, both externally and internally, was always followed by the reduction of fever and improvement of the diarrhoea.

The internal use of cold water given freely is very often beneficial. The vomiting is often increased at first, but this does good by washing out the stomach. Afterwards a sedative effect is produced, which is a valuable step gained in that food and medicines are better borne. The use of cold drinks and cold applications is good in entero-colitis and gastro-enteritis.

In entero-colitis the fecal evacuations may be nearly uniform, or they may change in color at different times. They contain altered epithelium cells, partly digested casein, and sometimes mucus or mucus streaked with blood. Besides the free use of cold water or ice internally and externally it is good to use enemata of tepid water or medicated water to wash out the lower bowel. Enemata are useful when the movements contain mucus with or without blood. By this means the colon is washed out. Their benefit is limited, however, for the tepid or medicated clysters can not go beyond the ileo-cæcal valve, and often the small intestines are the seat of most of the inflammation.

I have not enough experience with washing out the stomach to say much for or against it. I have known of deaths occurring while one or both of these treatments were being used. In the last stages, when collapse is present, I hardly think they are admissible.

In cholera infantum, when the child has the characteristic stools, viz: an acid, greenish-yellow fluid containing lumps of undigested food and casein, and, later on, evacuations similar to the discharges of Asiatic cholera, absolute rest of body and abstinence from food for twelve or fourteen hours are indicated. During this time plenty of cold water to drink or a piece of ice to suck or swallow, if the child is old enough.

Impure air is also one of the causes of intestinal diseases of children in hot weather. The first three years of my practice in Philadelphia I attended, during the summer months, a great many children suffering with intestinal diseases in one

of the poor sections of the city. The sanitary condition of the houses and neighborhood was deplorable. The water-closets were filled to overflowing, the streets were dirty, and decaying portions of vegetables were exposed to the heat of the sun. As a result of this impure air the death-rate was very high, and could only be lowered by getting the parents to take their sick children to some free sanitarium from day to day.

The use of improper food is another cause of intestinal diseases in hot weather. The mother's milk is the proper food for children. It is, however, exceptional for a mother to be able to nurse a child the entire first year of its life, so that a resort to other foods is wholly or in part a necessity. I have almost abandoned the use of milk foods. It has been my experience that children using them do not grow so strong, muscular or so rapidly as they should. When the mother's milk fails, or when it is possible to nurse the child only in part, my preference is for sterilized milk. Cow's milk, due to the handling it undergoes, is apt to disagree with children in hot weather; but when it is given sterilized, intestinal diseases are much less frequent. In some cases no dilution of the milk is necessary, as I have known many children fed on cow's milk from birth and it agrees well with them when obtained fresh. I attend one large family of children who are fed in this way, and none of them have ever suffered with intestinal diseases.

*Prophylaxis.*—In intestinal diseases of children prophylaxis is very important. Give the child plenty of cool, fresh air, without exposure to the intense heat of the sun. Sunshine in moderation is beneficial, as it develops the red blood corpuscles and prevents anæmia. The advantages of sunshine are seen in both the vegetable and animal kingdoms. According to Dalton, the tadpole requires nine months in the shade to change to a frog, whereas in the sunshine it takes but three. The dress is important also. Flannels should be worn all the year round, and a thin abdominal bandage day and night. The child should be bathed morning and night, kept as cool as possible during the heat of the day, and have cold water to drink and cold sponge baths to the head. By care and these particulars sickness may often be avoided and lives saved that would otherwise be lost.

*Therapeutics.*—In entero-colitis always begin with castor oil, guarded, if necessary, with opium; or calomel and bicarbonate of soda, if the fecal evacuations show a tendency to acid fermentation; if alkaline, bismuth subnitrate or subcarbonate may be used in place of the soda. Calomel and bismuth are antiseptic and antiemetic. Bismuth is also mildly astringent, and its local action on the inflamed mucous membrane is sedative. If there are no indications of convulsions, stupor or collapse, opium in small doses combined

with pepsin, or with pepsin and bismuth, answers well. The opium arrests the peristaltic action of the bowels and quiets the nervous system, while the pepsin aids digestion. Bromides and assa-fœtida may often be used in place of opium. When the nervous symptoms preponderate, equal parts of turpentine, sweet oil and laudanum, heated as hot as can be borne by the nurse's fingers, should be rubbed down the spine twice a day; and when pale, limpid urine is passed, it is more important to attend to it than to highly colored urine; for when it is pale and limpid a neurotic state of the kidneys exists, and powerful nerve stimulants should be given.

In cholera infantum very much the same treatment should be adopted, but stimulants should be used more freely. Probably the heroic treatment of the future, when other means fail, will be to open the abdomen and wash out the whole of the intestinal tract.

In all acute and chronic cases of intestinal diseases of children I cannot speak too highly ofunctions of almond or olive oil. If the child is rubbed two or three times a day with oil, an improvement in its condition is soon apparent. The advantages of this treatment are: First, a reduction of fever soon after the oil is applied; second, it nourishes and supports the child, which is a great desideratum when digestion is carried on imperfectly; third, it regulates the functions of the skin, which, when hot and dry, regains its natural moisture after the use of the oil. Effete material is more readily eliminated, the epithelium is softened, and the transudation of gases takes place more rapidly through the skin, oxygen being absorbed and carbonic acid gas thrown off. The importance of and benefit to be derived from bathing was early recognized by the ancients. Under the Roman emperors the baths attained a grandeur and magnificence that almost challenges belief. A great number of acres were covered by the baths of Diocletian and Caracalla. The world recognizes that the system of bathing attained its greatest perfection in the Roman empire during the days of Celsus.

At the present time there is a tendency to appreciate more fully the advantages of bathing, not only as an essential and necessary means of cleanliness, but also as a therapeutic agent for relieving, and sometimes curing, many obstinate and chronic diseases which do not respond readily to other modes of treatment.

The pepsin used should be soluble and as pure as possible. An insoluble pepsin contains inspissated mucus and ptomaines, and realizing that there is a great difference in the activity of the various preparations of pepsin, and the importance of selecting the best variety, I decided to test some of the pepsins of the market. The samples were procured from a druggist from the pepsins he had in stock. They were prepared

and labeled Nos. 1, 2, 3 and 4. Each sample contained a triturate composed of one-tenth of a grain of pepsin and nine-tenths of a grain of milk sugar. I did not know, at the time I procured the samples, whom they were manufactured by.

*Test.*—Several eggs were boiled for fifteen minutes, allowed to cool, and the coagulated albumen was freed from the yolk and superficial moisture, then pressed by a spatula through a brass sieve having thirty meshes to the linear inch. After thoroughly mixing the moist and divided albumen I weighed out and transferred 200 grains of it to a mortar; 110 ccm. of water acidulated with hydrochloric acid, in the proportion of 50 minims to the pint, was used, and the albumen carefully triturated with the same. The water was used in portions, so that a uniform division was obtained of the particles. This was transferred to the small cylinder placed in the apparatus, to which a water bath is attached, and where a temperature of 104° F. was sustained for six hours with frequent rotations of the digestive fluid by the pistons of the apparatus. After the stated time of the operation the cylinders were cooled and the activity of each pepsin as to its digestive power was noted. No. 1 was the only one which had digested all the albumen. This potent production is known as pepsin purum in lamellis, and is manufactured by Parke, Davis & Co. As nearly as I could ascertain without weighing the albumen in the other tubes, No. 2 had digested  $\frac{7}{10}$ , and Nos. 3 and 4 about 30 per cent. of the albumen in the respective tubes. The other specimens of pepsin tested were: No. 2, Fairchild's; No. 3, Boudault's; No. 4, Proctor's.

DR. J. SOLIS-COHEN, of Philadelphia, commended the use of cold water and ice externally as a means of reducing temperature, and deprecated the exhibition of the chemical antipyretics, which are usually cardiac depressants, and which aggravate the tendency to heart failure.

DR. J. A. JEFFRIES, of Boston, also advocated external cold.

DR. J. A. LARRABEE, of Louisville, considered it of great importance for the proper application of therapeutics to distinguish between the various diarrhoeal diseases. Are all these diseases the same, and do they demand the same treatment? In one class could be placed thermal diarrhoeas. The condition of the patient was similar to that in sunstroke, and the therapeutic indications were identical. Here the remedy, *par excellence*, is the external use of cold. He differed with Dr. Hooper in his conception of the term cholera infantum. Cholera infantum is a disease in infants similar in its clinical manifestations to cholera in the adult. It is in all probability caused by ptomaines. It is not usually preceded by ordinary diarrhoea, but begins suddenly. From the first, then, is the characteristic vomiting and their

watery stool. There is rapid abstraction of serum from the blood and the child quickly becomes pale, pinched, blue and cold and, unless relief quickly comes, dies. Cases of this kind must be differentiated from thermal diarrhoea and the other forms. Therapeutic measures must be immediate. There is no time for the exhibition of the ordinary remedies. For ten years he has been in the habit of treating these cases by the hypodermic injection of morphia and atropia. He gives about  $\frac{1}{2}$  gr. morphia and a very small amount of atropia to a dose. A convenient method is to dissolve a tablet containing  $\frac{1}{4}$  gr. morphine and  $\frac{1}{80}$  gr. atropin in an ounce of water and inject 10 drops in a child 1 year old. This treatment has been very successful. For the often following diarrhoea he resorts to antiseptics, and chief among them he ranks calomel; for enterocolitis he prefers evacuates in the early stages. He has great faith in salines to relieve the strangulation of the vessels. For chronic cases he has had good results from frequent inunctions of oils.

DR. WM. PERRY WATSON considered it very important, as a prophylactic against diarrhoeal disease, to keep the legs and lower part of the body warm. In many cases milk, however prepared, cannot be retained. When this is so he stops the administration of milk and gives oatmeal water seasoned with salt and sweetened with sugar. It is given cool, in small quantities at a time, and at regular intervals. In the meantime, if the child cries, a little hot water may be given. It is an excellent remedy for ordinary colic. Cholera infantum usually follows other forms of diarrhoea, but may occur suddenly. It usually comes on the third or fourth of a series of hot days.

DR. E. F. BRUSH said that by visiting cow pastures one could predict the occurrence of epidemics of diarrhoeal diseases among infants. In favorable localities, when grass is good, cows refuse to eat certain weeds, as lobelia, poison ivy, buttercups, etc. Little clumps of these weeds may be seen dotting the pasture. When hot, dry weather comes and the grass is scarce, the cattle eat these weeds and the poisons taken by the cow are excreted in the milk. These poisons are gastro-intestinal irritants and give rise to cholera infantum in bottle-fed babies. Such milk even poisons and sometimes kills sucking calves. His treatment was to stop the milk and give chloroform in emulsion with castor oil and gum arabic. He condemned the use of artificial commercial foods. He had investigated the manufacture of these foods, and he had found that they were too often made of various refuse materials. When a manufacturer had a waste product that he did not know what to do with he made it into an infant food. He knew of one that was made of salmon roe and another from the whey from a cheese factory. One preparation of beef in the market was

made of the blood from slaughter-houses, preserved with whisky. The great advantage of the home preparation of food was that it was then known what was being given.

DR. I. N. LOVE said that he would use commercial foods as he would drugs—with great discretion, and never when other means were at hand and equally good. These foods were tools, and the physician can not always stop to make them. Again, it is not always possible to get what we wish at the homes of patients. Home manufactures can not always be trusted. He was sorry to learn that men engaged in the manufacture of these foods could be so base as to put filthy refuse on the market for so sacred a purpose as the feeding of infants. He could not condemn too severely such action, but he could not believe that all manufacturers were so dishonest.

#### A RARE CASE OF PRIMARY LYMPHOID TUMOR SPRINGING FROM THE FLOOR OF THE RIGHT PYRIFORM SINUS. REMOVAL THROUGH THE NATURAL PASSAGES. PERMANENT RECOVERY.<sup>1</sup>

*Read in the Section of Laryngology and Otology, at the Fortieth Annual Meeting of the American Medical Association, June, 1889.*

BY JOHN NOLAND MACKENZIE, M.D.,

PRESIDENT OF THE AMERICAN LARYNGOLOGICAL ASSOCIATION; PHYSICIAN IN CHARGE OF THE DEPARTMENT OF LARYNGOLOGY AND RHINOLOGY IN THE JOHNS HOPKINS HOSPITAL DISPENSARY; CLINICAL PROFESSOR OF DISEASES OF THE THROAT AND NOSE IN THE UNIVERSITY OF MARYLAND; AMERICAN EDITOR OF THE JOURNAL OF LARYNGOLOGY AND RHINOLOGY; SURGEON TO THE BALTIMORE EYE, EAR AND THROAT CHARITY HOSPITAL, ETC.

Mr. C., æt. 42, 5 ft. 10 in. high, weight 220 lbs., of Leesburg, Va., a prominent divine of the Methodist Episcopal Church, South, consulted me May 4, 1885, on account of an obstruction in the throat which seriously interfered with his vocation as a public speaker and which, when he assumed the recumbent posture, threatened suffocation from pressure on the windpipe.

Mr. C. was otherwise in perfect health and could assign no cause for the existing state of affairs. Deliberate and natural in his style of declamation, he had occupied the pulpit without detriment to his vocal organs for over twenty years. Although convinced that the trouble causing the obstruction originated at an earlier date, the first time he felt sure there was anything the matter with his throat was about eight months prior to the time at which he came to me for advice. At that period he became aware of a sensation which he compared to a piece of phlegm in the throat which seemed fastened to

the epiglottis, and which could not be removed by expectoration. Soon after, difficulty in public speaking was experienced; the throat would clog up when it became dry in speaking or when an effort was made to swallow. At the same time something would seem to sink down into the throat and close up the windpipe. He consulted his physician in Warrenton, Va., where he then resided, and was told that the uvula was elongated and lying on the tongue, and was given astringents to contract it. Several months of this treatment failing to remedy the disorder, he had the uvula "clipped" by a physician in Baltimore. This failing also to relieve, he returned to his native place and again consulted his former adviser, who found the soft palate considerably inflamed and the whole palatine arch in a relaxed condition, so that the mucous membrane "sagged down like a wet sheet." This condition was dissipated apparently by a few weeks' treatment with ordinary sprays, but after the parts became normal, he was still conscious of the obstruction to respiration. He again sought advice, insisting that there was something in the larynx. By depressing the tongue and causing retching, his physician discovered the upper portion of what he took to be a growth upon, or hypertrophy of the epiglottis, and advised him to consult a special surgeon at once.

At my request, Mr. C. prepared a detailed history of his case from which I take the following extract, in view of the interest attaching to the symptomatology of this class of growth: Prior to the discovery of the obstruction, "changes in the voice in preaching would occur in the same day, and sometimes in the same sermon. Sometimes the voice would be heavy and harsh in the morning, and difficult to control, and at night more flexible and easier to manage; or *vice versa*. Now it is disposed to be smothered, and I cannot with any comfort sing. This is its condition all the time. It was only when the growth began to impinge upon the epiglottis that the choking began. There is no soreness. I cannot lie on my left side and sleep. If I turn into this position at night I cannot get my breath. The growth seems much larger at some times than at others. Extreme cold or heat affect it. I cannot have comfort in a crowded, warm place. A temperature of about 50° F. seems to suit it best. Deglutition of dry food is impossible; it seems to adhere to the surface of the growth and stop the passage of air to the lungs. Speaking does not appear to injure it, but, on the contrary, it sometimes gives less annoyance after preaching than before, especially if the temperature of the room is not too high. It feels as hard as a piece of tender beef, but not larger than it did six months ago. Astringents seem to cause it to swell up instantly. Several times before I knew what it was, muriated tincture of iron was applied as far down as possi-

<sup>1</sup> The growth was presented before the Medico-Chirurgical Faculty at its meeting in 1885 (*vide Transactions*).

ble with the effect of stopping my breath. Recently, any violent exercise, which rapidly increases respiration, causes the growth to swell. The same is true of any nervous excitement."

Examination of the throat was rendered difficult by the large size of the patient's tongue, which, when protruded, occupied almost entirely the buccal cavity and prevented the satisfactory introduction of the laryngeal mirror. Laryngoscopy was therefore undertaken with the tongue depressed, as much as possible, by means of a spatula. Only the right half of the larynx could be seen, the left being covered by a large smooth, globular, bright-red mass which extended from a point a little to the left of the median line to the right lateral wall of the pharynx, filling the corresponding pyriform sinus, from which cavity it apparently sprang. The growth was distinctly movable both on manipulation and phonation. It could just be reached with the finger and communicated to the touch the sensation of a soft elastic, semi-solid body, with here and there small areas of a harder substance. By exciting retching, the upper surface of the tumor appeared above the upper edge of the epiglottis.

On May 5, I operated as follows: Having provoked retching, the growth was caught with a pair of laryngeal forceps in its ascent and drawn as far upward as possible toward the base of the tongue. The handles of the forceps were then entrusted to my friend, Dr. S. Johnston, who was kindly present, and upon the forceps as a guide, the strong silver wire of an *écraseur* was threaded and carried to the base of the growth, which was then rapidly severed, the whole operation taking only two or three moments. The patient expectorated no blood after the extirpation of the growth.

Laryngoscopic examination immediately after the operation discovered in the centre of the floor of the right pyriform sinus a small raw, slightly bleeding surface which marked the site of the tumor's base. The patient thought that, during the night, some hæmorrhage took place from the wound, the blood entering the stomach, but on the following morning, a firmly organized clot occupied the seat of operation and the patient was allowed to return to his home in Virginia.

The growth was about the size and shape of a testis, was soft and elastic to the touch and gave a distinct sense of fluctuation. On section, it appeared to be made up of a soft elastic tissue in which innumerable tolerably hard whitish points were seen. Microscopical examination undertaken by Professor Councilman, of the Johns Hopkins University, disclosed the following: The growth was covered over with epidermis which showed in several places slightly rough elevations. Under the microscope, were found "externally, well-formed mucous epithelium, while the body of the tumor was composed of areolar connective tissue in which there were small areas of small cells

similar to the lymphoid corpuscles. Immediately beneath the epidermis, this lymphoid tissue was most abundant. There was no glandular tissue in the growth nor any glands opening on its surface. The small cell areas could well belong to the follicular tissue so common in the pharynx."

In other words, the tumor was composed of the lymphoid pharynx tissue so graphically described in recent years by Waldeyer and his pupils, and I have therefore used the term "lymphoid" as best expressive of its true nature.

The origin of the growth was doubtless due to some form of local irritation—possibly in the case before us to a neglected localized inflammation of the pyriform sinus.

Outgrowths, generally fibrous in nature, are occasionally met with in the glosso-epiglottic fossæ, or projecting from the tonsils and lateral pharyngeal walls, but primary growths of the pyriform sinus are excessively rare. As the above case is probably unique, I have thought it worthy of record.

Over four years have elapsed since the removal of the growth without any signs of its recurrence.

DR. J. SOLIS-COHEN remarked that it was rather curious that this unique growth originated in the position from which some few cases of lipoma had taken origin.

## IMPAIRED VISION AS THE RESULT OF SUNSTROKE.

*Read in the Section of Ophthalmology at the Fortieth Annual Meeting of the American Medical Association, Newport, R. I., June, 1889.*

BY A. R. BAKER, M.D.,  
OF CLEVELAND, O.

My attention was called to this subject a few years since by the commissioner of pensions, who referred a number of cases to me for expert examination for alleged impaired vision as the result of sunstroke while in the service. Upon referring to works upon the eye and special articles treating the subject of sunstroke, I found little of value bearing upon this point. Most articles discussing the etiology of atrophy of the optic nerve mentioned sunstroke as one of the causes; and treats upon the sequela of sunstroke mentioned blindness as one of them. But as to any information as to the frequency of atrophy of the optic nerve as the result of sunstroke, or as to the pathological conditions, the symptoms, diagnosis or treatment, these works make no mention; and the only report of cases that proved of any value in my researches was that of Dr. Hotz, in a paper entitled "Notes of Intra-ocular Lesions Produced by Sunstroke" (*American Journal of Medical Sciences*, July, 1879). In this paper Dr. Hotz reported a number of cases in which an ophthalmoscopic examination shortly after the sunstroke revealed an optic neuritis. In

none of these cases was the swelling of the optic nerve excessive, and all recovered with vision little, if any, impaired, and a very slight, if any, atrophy. In the *Medical Record* of April 28, 1888, there appeared a paper by Dr. Thos. A. Spaulding, of Portland, Me., on the subject, a part of which was read at the preceding meeting of the American Ophthalmological Society. In this paper it is stated that "no member present had ever heard of the sight being affected by sunstroke." As this statement appeared to be somewhat remarkable I addressed letters to a number of physicians who, owing to long experience in military and civil practice, I thought would have met such cases; but all the physicians to whom I addressed these letters answered that they had never met a case of blindness or impaired vision as the result of sunstroke.

Among 13 cases referred to me for expert examination with impaired vision, alleged as the result of sunstroke, I met three cases of simple hypermetropia, two of senile cataract, one of progressive myopia, one of detachment of the retina, and one of disseminated choroiditis, probably of syphilitic origin. Judging from these cases, and from the almost entire absence of references to this subject in medical literature, I am not surprised that many observers are inclined to doubt the existence of impaired vision as the result of insolation. I wish to put on record the following cases, which, to my mind at least, present conclusive evidence that vision is sometimes impaired as the result of sunstroke; and it is to be hoped that in the future the fundus of the eye will be carefully examined in all recent cases so that the frequency of optic neuritis as the result of this cause may be determined.

*Case 1.*—Mr. H. M., aged 39, examined April 25, 1887. Had sunstroke while in the service July, 1864. Has had neuralgia and pain in the head almost continuously ever since; this is especially severe when exposed to heat. He followed his usual occupation as a miner for some years after returning from the army, but gradually became unfit for work and now has partial paralysis of upper extremities. He has complained of impaired vision ever since he came out of the army, his sight being poor especially at night. Never associated the loss of sight with sunstroke. No other cause for neuralgia, paralysis, loss of sight and other nervous affections can be discovered. Partial white atrophy of optic disc; field of vision very much contracted; vision, left eye,  $\frac{2}{30}$  (Snellen); right eye,  $\frac{2}{40}$ ; refraction normal. A record taken five years previously showed no appreciable change in his field of vision.

*Case 2.*—Mr. A. J. W., farmer, aged 65; examined August 1, 1887. Had sunstroke in June, 1864. Has suffered from constant headache confined to right side of head. This side of the head is always more or less tender on pressure. Mind

not very clear; prematurely old: slight paralysis of left side of body; dragging of left foot in walking; cannot bear heat of sun; always carries an umbrella when sun shines. Has fallen to the ground frequently during hot weather, and only resuscitated by cold water affusions. Complete white atrophy of outer half of optic disc of left eye, and inner half of right optic disc: left lateral hæminopsia; vision, left eye,  $\frac{2}{100}$ ; right eye,  $\frac{2}{100}$  (Snellen). I examined the eyes with the ophthalmoscope before taking field of vision, and was able to say, from the atrophic condition of the outer half of one optic disc and the inner half of the other, that the patient was suffering from hæminopsia.

*Case 3.*—Mr. J. T., aged 45; examined November 5, 1888. Had sunstroke in summer of 1864. Has been a constant sufferer from neuralgia, photophobia and other nervous affections since date of sunstroke. Has never been able to engage in any business or occupation. Does not venture outside of the house on days when the sun is shining. He requires the same constant care and attention as a child six or eight years of age. There is complete white atrophy of the optic nerve of left eye. Veins are large and arteries very small. The blood-vessels about the disc are very tortuous, showing previous intense neuritis. Partial white atrophy of right optic disc. Blood-vessels somewhat tortuous, but not so much so as in the other eye. Vision left eye, slight perception of light; right eye,  $\frac{2}{150}$  (Snellen).

*Case 4.*—Dr. T., aged 57; examined April 15, 1889. In June, 1863, while in charge of a picket line as medical officer, he became insensible from sunstroke. He was totally blind for three days. His sight gradually returned, but with the field of vision extremely limited. He describes it as looking through two small gimlet holes. The brightest day appears to him as mere twilight, and at night he is almost completely blind. He has lost all color perception. Although he has had to avoid walking on the streets on hot days, and his general health has not been robust, he has proven himself a man of indomitable will, and, notwithstanding his impaired vision, he has been a successful practitioner of medicine, and still continues to do an office practice. He has white atrophy of both optic nerves of such a high degree that it seems remarkable that he can see at all. The field of vision is only about two inches in diameter at a distance of 12 inches. Vision right eye,  $\frac{2}{100}$ , with 2 D. C. axis  $90^\circ = \frac{2}{80}$  (Snellen); vision left eye,  $\frac{2}{100}$ , with 2 D. C. axis  $90^\circ = \frac{2}{100}$ .

In addition to these cases, all of which occurred in old soldiers, I wish to report the following case, which very closely resembles those reported by Dr. Hotz:

Mr. H. B., aged 45, merchant. Had sunstroke on July 4, 1886. First examined on August 5th

of the same year. Patient suffering from headache, dizziness, nausea, occasional diplopia and dimness of sight. Ophthalmoscopic examination revealed an optic neuritis of both eyes; outlines of the disc could not be distinguished. Veins large, arteries small. Vision, right eye,  $\frac{20}{20}$ ; left eye,  $\frac{20}{20}$  (Snellen). Refraction normal. Have had the case under observation most of the time since the above date. At present there is no appreciable atrophy of optic nerve. There is a slight tortuosity of blood-vessels. Vision  $\frac{20}{20}$  in either eye. Health good. No nervous disturbances except that the patient seems to be afraid that there is something serious going to happen, and makes the life of his medical adviser a burden by constant inquiries after this or that insignificant symptom.

In view of these cases, notwithstanding the fact that out of thirteen cases of alleged impaired vision as the result of sunstroke nine were found to be suffering from affections that could have no possible connection with this cause, I am led to believe that impaired vision does result from sunstroke in a large number of cases. We would expect this from an affection which produces such a profound impression upon the cerebral centres.

It is not necessary for me, before such an audience as this, to enter into a detailed account of the intimate relation existing between the optic nerve and the brain and its meninges. I wish simply to emphasize the importance of making an ophthalmoscopic examination of the *fundus oculi* in all cases of *coup de soleil*. This examination should be made immediately after the attack, at a somewhat more remote period, and in all cases where there is alleged impaired vision as the result of sunstroke, no matter if it be at a period many years afterward.

## RELAXATION AND MANAGEMENT OF THE PERINEUM DURING PARTURITION.

*Read before the Golden Belt District Medical Society of Kansas, July 1, 1889.*

BY WILLIAM B. DEWEES, A.M., M.D.,  
OF SALINA, KAN.

*Mr. President and Fellows of the Golden Belt District Medical Society of Kansas:*—In performing the duty assigned me on this occasion, I have chosen to briefly consider the *relaxation and management of the perineum during parturition*.

Great rigidity of the tissues at the pelvic outlet, as a cause of lacerations and other serious complications in labor, is—as we are all fully aware—an old topic, and almost worn threadbare from discussions *pro* and *con* as how the better to overcome this abnormal condition; nevertheless the little triangular, pyramidal or wedge-like body, known

as the perineum, often meets with a serious lesion, occurring as an accident to parturition.

Believing that immunity from perineal injuries is due to a better knowledge of preventive means, we offer no apology in presenting the subject for your consideration.

Prof. H. Lenox Hodge,<sup>1</sup> writing on this subject, says: "There are few complications which demand the more sedulous attention, and the best exercise of the judgment and skill of the accoucheur."

Prof. Wm. P. Dewees<sup>2</sup> observes: "There is no more frequent complication of labor, or one more productive of dangerous consequences to the mother and child."

The very great variety of opinion, by those who write and teach, as to the best mode of caring for the perineum, sets forth the necessity for a closer study and fuller discussions of the subject. One of the most delicate as well as most responsible tasks which devolve upon the accoucheur is the regulation of the exit of the child's head and consequent management of the mother's perineum. He who preserves the integrity of a perineum which is in peril, shows more skill and consummates higher art than he who successfully repairs a perineum which has been *torn*.

The method of universal success has not been found, nor can it be confidently hoped for. However, better methods with better results may be expected. Under any method of management yet devised, injury occurs in a considerable number of cases. The history of accidental parturient wounds of the perineum proves that they occur in the experience of every practitioner of obstetrics, however skilful he may be. But, it cannot be denied that they occur most frequently in the hands of the unskilful; that a large percentage of such cases are avoidable, and that many others, by prompt and well directed assistance, may be limited in their extent.

The question of the proper management of the perineum during labor is no longer dwelt upon in our schools as formerly; indeed, in some it is not taught at all, the direction being "if the head be delayed, place the forceps, and pull it through; a few stitches will make it all right." How different this, from the instructions imparted in my *Alma Mater*;<sup>3</sup> how well do I remember that venerable teacher, Prof. R. A. F. Penrose, folding a napkin to a soft smooth surface, and placing it upon the distended perineum of a manikin, assuming a position to support against the advancing head. "Gentlemen," said he, his face reflecting the conscious responsibility and anxious interest which should be felt by every one who assumes to aid the physiological act of parturition, at the moment when the future happiness and

<sup>2</sup> Dewees' System of Midwifery, p. 358.

<sup>3</sup> University of Pennsylvania, Med. Dept., at Philadelphia.

comfort of a suffering woman is depending upon a tear, or no tear, "how long should you hold your position here?" "I answer one hour, two or three hours if needed, until this head is extruded and this perineum saved." "Remember the law; every perineum will properly distend if time be given to prevent rupture."

This early imbued attention to the perineum has saved many a one under my care. But in the light of our present knowledge it may be carried too far. The question of "how long shall we wait?" takes a new point of consideration. The condition of the child and mother come earlier into account.

From great rigidity of the perineum and adjacent soft parts, and strong, violent contractions of the uterus, there has occurred:

1. Death of the child.<sup>1</sup>
2. Rupture of the uterus and death of the mother.<sup>2</sup>
3. Laceration of the perineum and sphincter ani.<sup>3</sup>
4. *Convulsions and violent spasms*, from prolonged pressure of the fetal head on the obturator nerves and sacro-sciatic plexuses. Such irritations being propagated to the spinal marrow and brain, disturbing their functions; hence these excitations.<sup>4</sup>

5. *Inflammation and mortification*, which has sometimes proved fatal; and in other cases, though the mother recovered, she has been subject to an involuntary discharge of fæces and urine through the vagina.<sup>5</sup>

6. *Atony of the uterus*; the contractions being thus insufficient to expel the fœtus, even though the rigid soft parts should then become relaxed.<sup>6</sup> Delivery being now accomplished with the forceps, yet the injury does not end here; from inability of the uterus to contract, an hæmorrhage supervenes, which is generally fatal to the mother.<sup>10</sup>

And when we add to these, the risk of rupture of the blood-vessels;<sup>11</sup> fatal congestions of brain and spinal marrow, also in the viscera of the chest and abdomen;<sup>12</sup> death from exhaustion of vital power or, according to Dr. Churchill, of the "nervous shock."<sup>13</sup> While, even when every precaution is taken, there are cases in which extreme smallness of the vulva, and rigidity of the soft parts, with a disproportionately large fœtal head, make it impossible for the head to be expelled without greater or less rupture of the perineum.<sup>14</sup>

All of which have happened, and may again happen under similar circumstances. We cannot suppose that any great advantage can be derived from "waiting patiently for the efforts of nature," in complicated and protracted cases.

Having pointed out some of the evil consequences arising from a rigid state of the perineum and adjacent soft parts, we proceed to the consideration of the means by which to relax and give distensibility to these tissues, that they may sufficiently dilate in due time, and these evils be remedied. We shall notice:

*First*.—Some of the various methods as practiced and recommended by those who write and teach on this subject.

*Second*.—The means which a diligent and earnest endeavor to relieve the suffering incident to rigidity of the perineum and adjacent soft parts, by an impartial and unprejudiced examination of facts, and the dictates of reason; it has been my privilege to witness the beneficial results of the intelligent application thereof, at the bedside of suffering woman.

The practice of caring for the perineum has been in vogue since the days of Avicenna, almost 1,000 years. The various methods taught and practiced, as found in the literature on this subject, we shall endeavor to give in a brief *résumé*. The former plan recommended, according to Galabin,<sup>15</sup> was to press with the palm of the hand upon the perineum, when stretched over the advancing head, and so check that advance."

Baudelocque<sup>16</sup> firmly supported with the palm of the hand during a pain, and attempted forcible dilatation of the vulvar outlet during the interval.

Velpeau<sup>17</sup> advises the hands so placed that the radial side of the forefinger is in relation with the fourchette.

Ramsbotham,<sup>18</sup> resting his elbow upon the head, placed his hand against the perineum.

Depaul<sup>19</sup> places two fingers of the left hand on that portion of the child's head corresponding with the anterior commissure of the vulva, and two fingers of the right hand over that portion which corresponds with the posterior commissure, and thus counterbalances the effect of the uterine contractions.

Collins<sup>20</sup> applies the palm of the hand direct to the perineum during pain, with a soft cloth intervening. This plan was adopted by Meigs and Penrose, of Philadelphia, Pa. Glisan<sup>21</sup> teaches the same plan without the cloth.

Chailly<sup>22</sup> placed the patient on her back and

<sup>22</sup> System of Obstetrics, 1884, p. 210.

passed his right arm under her right thigh, and pressed his palm on the perineum, with the radial border of the index finger upon the outer border of the perineum, and the thumb extended on the right thigh. He at the same time placed his left arm over the thigh, with the fingers upon the vertex, for retardation and support. This is called the *Vienna* method.

Schröder<sup>23</sup> directs pressure upon the head, through the perineum, with the ball of the thumb or the fingers, for both support and retardation.

Lusk<sup>24</sup> gives direct pressure with the flat hand to the perineum in cases where central perforation seems imminent, and where there is defective elasticity he passes the left hand between the thighs and presses the head forward and inward, at the same time preventing undue extension by pressing backward through the perineum with the disengaged hand.

Niemeyer<sup>25</sup> advises pressure on the perineum in the direction of the axis of the inferior strait; more, however, with a view to extension of the head than of direct support.

Cazeaux,<sup>26</sup> in the former edition, says: "Press the whole perineal surface equally, and with a moderate degree of force, by the palmar face of the hand." But in the last (seventh) edition<sup>27</sup> the views of Goodell are recommended, both by Tarnier and Hess, the American editor.

Goodell<sup>28</sup> holds the head back by placing his thumb against the occiput, while drawing forward the perineum by hooking one or more fingers in the rectum.

Hodge<sup>29</sup> placed the finger over the posterior commissure of the vulva, so as to give it a firm support; at the same time the fingers of the other hand, upon the occiput, may prevent any sudden exit of the head.

W. Tyler Smith<sup>30</sup> advised holding back the head with one hand, with the other making the degree of distension.

McGaughey<sup>31</sup> supports the perineum by placing the right hand with palm on the centre of that body, with the fourchette between the thumb and forefinger, while the left hand is placed over the thigh, with its palm upon the head and the fingers touching the anterior thinned edge of the perineum, to hold back the head and at the same time to direct it forward.

W. A. Duncan<sup>32</sup> simply applies pressure to the advancing head, with the fingers in the shape of a cone.

Hohl<sup>33</sup> grasps the occiput with the hand, the

thumb above and the fingers below, thus holding back the head during a pain.

Garrigues<sup>34</sup> makes moderate pressure with the flat hand, so that the fold between the thumb and finger rests upon the posterior commissure.

Robert Barnes<sup>35</sup> applies the palm of the hand, so spread out as to rest upon the coccyx behind, and upon the pelvic floor, at the same time pushing up the skin from adjacent parts toward the fourchette.

Playfair<sup>36</sup> says: "If, when the head is distending the perineum greatly, the thumb and forefinger of the right hand are placed along its sides, it can be pushed gently forward over the head at the height of the pain, while the tips of the fingers may at the same time press upon the advancing vertex, so as to retard its progress if advisable." He thus aims with a view to relaxation rather than support.

Gardner<sup>37</sup> follows the same method as Playfair, but with a view to support, not relaxation.

Fasbender<sup>38</sup> places the patient on her left side, then standing behind her, seizes the head, the index and middle fingers applied to the occiput and the thumb in the rectum. He is thus enabled to control the head during a pain. Between the pains, he claims, the head can be pressed forward with the thumb, at the will of the operator.

Parvin<sup>39</sup> advocates applying the concave palm of the right hand to the convexity or the bulged perineum, while the left hand, passed over the right thigh, grasps the head and retards or directs it at will.

Reamy<sup>40</sup> says: "Place the patient on her back across the bed, with her nates brought to its verge: the thighs are flexed upon the abdomen, and the legs upon the thighs, with the knees close together. The limbs are held in this position by two assistants, one on each side sitting on the edge of the bed, with their backs toward the patient's head, who are given opposite ends of a towel or bandage of linen, about 10 inches wide and 40 or 50 inches long, which is carried around the buttocks spread out smoothly, with its anterior or upper edge on a level with the fourchette. They are then instructed to make traction, during the pains, in such amount, in such directions, and with such part of the bandage as the accoucheur may direct."

Englemann<sup>41</sup> advocates the semi-recumbent position in labor as the best in ordinary cases, and thinks that in this position there is a certain amount of support, which does away with the old method, which he thinks usually does more harm than good.

Dumas<sup>42</sup> recommends a procedure which he designates "præ-fœtal dilatation of the vulva." It consists in introducing two or more fingers and the thumb of the right hand into the vagina, and fitting the hand on to the head, not exerting any force on the approaching head, but rather allowing it to push the hand in front of it, and thus take the place of a dilator.

Ritgen<sup>43</sup> advises introducing two fingers into the rectum, and pushing the fœtal head upwards and forwards in the direction of the vaginal orifice. Many other substitutes might be cited for the purpose of "perineal support" and "perineal relaxation" by men eminent in the profession, but I shall spare you the infliction; this sufficing to prove,

*First:* That the practice of caring for the perineum has been entertained by the leading obstetricians for almost ten centuries.

*Second:* That tearing of the perineum has been likewise recognized, as an abnormal concomitant to labor—hence the scientific attention for guarding this body.

In summarizing the methods practiced we find that they are of three distinct classes, viz.:

*First:* Perineal support.

*Second:* Perineal relaxation.

*Third:* Perineal abstaining.

The first class, or those who direct their attention with a view of "supporting the perineum," may be divided as follows: 1. Methods which aim at protection chiefly by applying direct to the perineum some artificial means of support.

As advocates of this class may be cited Baudelocque, Velpeau, W. P. Dewees, Ramsbotham, Barnes, Cazeaux, Meigs, Penrose, Neimeyer, Tarnier, Hess, Playfair, Collins, Glisau, Gardener, Gooch, Garrigues, Reamy and Opie.<sup>44</sup>

2. Methods which aim at protection by endeavoring to retard the rapid descent of the head, and at the same time afford direct support to the perineum.

As supporters of this class we find Schröder, Lusk, McGaughey, Chailly, Hodge, Parvin, Fashbender.

The second class, or those who direct their attention with a view of "relaxation of the perineum," may be divided as follows:

1. Methods which aim chiefly to prevent the rapid descent of the head by direct pressure upon it, in order to gain time for adequate relaxation of the perineum.

Among this class we find notably, Kohl, W. A. Duncan, W. Tyler Smith, E. Warren Sawyer, Meigs, Penrose, Goodell and Depaul.<sup>45</sup>

2. Methods which aim chiefly to accomplish relaxation by artificial means of forcible dilation of the vulvar and vaginal outlets—with the finger

or otherwise—some at the same time practicing a process of enucleation. As exponents of this class we cite Ahlfeld, Duke, Dumas, Olshausen, Ritgen, Smellie.<sup>46</sup>

3. Episiotomy as a *dernier ressort* in cases of extreme peril.

This practice has found able followers in Sir James Simpson,<sup>47</sup> Chailly-Honore,<sup>48</sup> Anna E. Broomal,<sup>49</sup> Manton,<sup>50</sup> Madden,<sup>51</sup> Fordyce Barker,<sup>52</sup> Tyler Smith,<sup>53</sup> Cazeaux.<sup>54</sup>

The third class, or those who direct their attention with a view of letting the perineum religiously alone—total perineal abstaining. This practice finds high authority in the writings of Hewitt<sup>55</sup> and Leishman.<sup>56</sup>

We thus find that by far the greater number of the authorities trust in some method of preservation, and that methods which combine judicious perineal support with simultaneous retardation of the fœtal head meet with most favor. Again, we find, "Naegle, Grenser, Kleinwachter and Matthews Duncan think that the plan by relaxation gives *no better* results than other methods."<sup>57</sup>

Parvin<sup>58</sup> says "perineal support is not likely to be abandoned, and he does not believe it can be replaced by hip bandages or rectal pressure."

Prof. Dumas<sup>59</sup> criticises the various methods of supporting the perineum, and comes to the conclusion that none of them are either scientific or satisfactory.

Playfair<sup>60</sup> says: "Much error may be traced to a misconception of what is required. The term 'supporting the perineum' conveys an unquestionably erroneous idea, and it is certain that no one can prevent laceration by mechanical support. If the term 'relaxation of the perineum' was employed, we should have a far more accurate idea of what should be aimed at; and if this be borne in mind I think it cannot be questioned that nature may be most usefully assisted at this stage."

Grailly Hewitt, Leishman, Goodell and other eminent authorities have with untiring zeal endeavored to show the evil effects likely to follow supporting efforts. They maintain that by pressure exerted in this fashion we not only fail to prevent, but actually favor, laceration, in consequence of the pressure producing increased uterine action just at the time when forcible distension of the perineum is likely to be hurtful. Hence the opinion, notably of Hewitt and Leishman,<sup>61</sup>

that the perineum ought to be left entirely alone, and that the head should be allowed to gradually distend it, without any assistance on the part of the practitioner.

The frequency of rupture of the perineum during parturition is variously stated, as is also the opinion of the delivery with forceps as a cause of this injury.

Tyler Smith<sup>62</sup> says "laceration of the perineum is no uncommon accident."

M. D. Mann<sup>63</sup> states, "It is quite common in primiparæ and after forceps."

F. A. Reamy<sup>64</sup> writes: "Perineal lacerations are far more common than is generally recognized by physicians and patients."

Dr. Tait<sup>65</sup> reported seventy ruptures in 142 primiparæ.

Prof. Braun's<sup>66</sup> division of the Vienna General Hospital, in 1,157 primiparous cases, rupture occurred but sixty-eight times.

D. Hayes Agnew<sup>67</sup> says: "Such accidents doubtless take place, in a large majority of cases, from ignorance or carelessness on the part of the medical attendant, and yet may and do occur in the hands of the most competent and expert practitioners." "It is only in unskilled hands that the forceps can be said to do harm in this way."

Fordyce Barker<sup>68</sup> says: "The forceps may be a mechanical cause of rupture, and they may be a most efficient means of preventing rupture, especially in that class of cases where injury to the tissues may result from long-continued pressure upon the perineum. The danger in the use of the forceps arises from the fact that they are used as instruments of direct traction instead of instruments to complete a normal process—a physiological delivery of the head." The late Prof. Geo. T. Elliott,<sup>69</sup> one of the most accomplished of obstetricians, with all his skill, failed to prevent this accident at times. He cites a specimen: "It became necessary to resort to the forceps, and although I used the smallest and lightest in my possession, and all due skill and care, an appalling laceration occurred, splitting the sphincter ani and the vagina throughout its whole length to the bottom of Douglas' cul-de-sac."

Prof. Peaslee<sup>70</sup> stated in a report: "I then applied Elliott's forceps, the head being high up in the superior strait. While making traction quite forcibly, but very slowly, the blades of the forceps sprung, and their descent cut through the sphincter ani, and about 1½ inch up the rectum."

Prof. Wm. Goodell,<sup>71</sup> speaking of the use of the forceps, says: "There is such an abuse of

this instrument that I sometimes think that Bau-delocque was right when he said that the forceps had done more harm than good. It requires great skill and judgment to end a labor with forceps. A physician from inexperience, or being demoralized by the long and tedious labor, is liable to use undue violence and deliver the head too quickly, or to make traction in the wrong direction. I have myself torn the perineum, and have seen many good physicians do the same. Tears of the perineum will occur whether the physician uses the forceps or not, but in the majority of cases they come from the abuse of the forceps."

Olshausen<sup>72</sup> reports, as the result of the preventive measures adopted at the clinic in Halle during a period of ten years, 21.1 per cent. of perineal injuries in primiparæ, and 4.7 per cent. in multiparæ. These percentages do not include slight tears confined to the perineum. He regards 15 per cent. not too high an estimate for the absolutely unavoidable lacerations due to defective distensibility of the perineum, and to the disproportionate size of the child's head.

Parvin<sup>73</sup> says ruptures occur in from 20 to 30 per cent. of primiparæ, and in from 5 to 10 per cent. of multiparæ.

Schröder<sup>74</sup> found that lacerations occurred in 37.6 per cent. of cases delivered in the dorsal position, and 24.4 per cent. in other positions. Schröder's statistics are very strong, as showing that ruptures of the perineum are more common when women are delivered upon their back—French position—than when placed upon their left side—English position.

The authorities hold the same general opinion, viz.: that the frequency of these accidental parturient lacerations of the perineum may be lessened from 5 to 10 per cent. with due exercise of care and skill. My own experience warrants the statement that they may be reduced to even a considerable less percentage than this. By practicing the management which I shall hereinafter describe, there occurred fifty-one lacerations of the perineum in 1,000 consecutive cases of parturition, under my care. Of these, twenty-four were slight, twenty-two considerable, and five penetrating deep into and almost entirely through the sphincter ani.<sup>75</sup>

This gives 5.01 per cent. of all cases—primiparæ and multiparæ combined.

(To be concluded.)

<sup>62</sup> Am. Jour. Med. Sciences.—Goodell.

<sup>63</sup> Trans. Am. Gyn. Soc., 1882.

<sup>64</sup> Loc. cit.

<sup>65</sup> This does not include slight tears confined to the fourchette. It should also be remembered that women of good development, and laborious exercise, constituted the greater portion of my cases, my practice being confined to a farming community—in town and country. There occurred 226 cases of well-defined rigidity among these 1,000 cases.

## THE CLINIC.

REGULAR SURGICAL CLINIC AT RUSH  
MEDICAL COLLEGE, CHICAGO,

OCTOBER 15, 1889.

BY CHARLES T. PARKES, M.D.,  
PROFESSOR OF SURGERY.

[Reported for THE JOURNAL.]

*Case 1.*—Mrs. H., Chicago, age 44, American, housewife.

*Gentlemen:*—This patient you will recognize as the one upon whom we performed vaginal hysterectomy, three weeks ago, for cervical carcinoma. She is perfectly well and desires to leave the hospital.

You will remember that the broad ligaments before division were secured by means of two pair of long-jawed forceps, for the purpose of preventing hæmorrhage, and no ligatures were used; and you will also remember that very little blood was lost at the time of the operation. The operation was finished at 2:30 P.M.; the patient was returned to the hospital and put to bed. She rested very comfortably until about 8 P.M., when she was seized with severe vomiting, and this was followed by profuse hæmorrhage from the vagina. I saw her within a few moments after its occurrence, exposed the parts and ascertained the cause of the hæmorrhage to be from the slipping of a part of the tissues grasped in the forceps placed upon the left broad ligament, which undoubtedly let free the uterine artery. The cause of this accident was the succussion of the vomiting secondarily; primarily it was rendered liable for the following reasons, viz: The use of the strong-jawed forceps is followed by a slough of all the tissues included in their grasp. This slough is slow in separating, gives rise to rather a foul discharge, and is accompanied with some danger of infection. With the intention of avoiding these conditions I attempted to apply this pair of forceps more loosely than heretofore. My idea was to make just enough pressure to control the bleeding, and not enough to kill the tissues included in the grasp of the forceps; hence I fastened it only by the first catch instead of shutting the handles down to the third notch. This controlled the hæmorrhage, but as soon as the straining of the vomiting came on the tissues pulled out of the grasp of the forceps and bleeding occurred immediately. Without anaesthetizing the patient an attempt was made to seize the bleeding vessels with other forceps, and believing that I had been successful I left the patient. Within half an hour I was informed that the bleeding had recurred as badly as ever. The patient was now anaesthetized and the parts thoroughly exposed, but no bleeding artery could be found. The entire surface and cavity were now thor-

oughly packed with strips of iodoform gauze and bleeding did not recur. The forceps were all removed at the end of forty-eight hours. The packing was gradually removed from day to day. The patient went as rapidly to recovery as if the hæmorrhage had not taken place. All things considered, it is perhaps the best plan to clasp the forceps as tightly as possible. Excessive hæmorrhage does not always retard the recovery of patients, although it should be the rule to use every precaution to prevent its occurrence.

*Case 2.*—Mrs. G., Baraboo, Wis., age 28, American, housewife. This patient, whose family history and previous history are good, has suffered for six months from some abdominal trouble. Inspection of the abdomen shows a decided bulging below the line of the umbilicus. Palpation determines the presence of a hard movable mass about the size of a coconut in the left lumbar and umbilical regions. Fluctuation is easily recognized. Below this mass, entirely across the body, percussion gives flatness everywhere except in the upper zone of the abdomen. Vaginal examination elicits the fact that the uterus is of normal size, retroverted and probably free from the mass above.

Diagnosis: Multilocular ovarian cyst, for the removal of which we will do a laparotomy. An incision 4 inches long is made in the median line through the abdominal walls between the umbilicus and the pubis. This incision should always reach near to the pubis, so that when the tumor is delivered the pedicle can be easily handled and managed. It should be made quickly through the tissues of the abdominal walls down to the transversalis fascia without the use of a director, the eye recognizing the different tissues as divided. A good guide for the place of the incision is the dark line to be recognized in the skin between the umbilicus and the pubis directly over the course of the linea alba.

When the transversalis fascia is exposed it should be seized with a pair of dissecting forceps in the hand of your assistant and another pair in your own hand at points one-half inch from each other, and be lifted up from the subjacent tissues and then freely divided with the knife. This will expose the peritoneum, which should be seized in the same manner and also lifted away from subjacent tissues and freely incised. This can be done with safety and without fear of injuring the sac, or intestine, or omentum, or whatever else may be beneath it. Now, while talking to you these steps have all been taken and here is an opening in the peritoneum, out of which flows a little peritoneal fluid, warning us of the fact that the peritoneal cavity has been reached. Through this opening I can see the white glistening surface of an ovarian cyst; and this is the sight which always gladdens the heart of the operator, for when he sees this white glistening

tissue he knows that he has an ovarian cyst to deal with. The diagnosis is confirmed, as all other outgrowths of the uterus and its appendages are reddish in color. The opening in the peritoneum is now enlarged to the full extent of the opening through the abdominal walls by means of the scissors, using the fingers in the abdominal cavity as a guide to avoid wounding the intestines, or omentum, or bladder, should they be in the way. The cyst wall now comes up freely in the wound, so that it can be seen in all parts of the room. Some authorities advise, and many operators practice at this stage of the operation, the plan of introducing a sound or the hand into the abdominal cavity and over the surface of the tumor for the purpose of ascertaining and locating adhesions. I do not think it a good plan and never practice it. No attempt to separate adhesions should be made until they can be seen and are under perfect control, and this can be better done after the sac is emptied and its surface, with the adhesions, is drawn to the opening in the abdominal wall. The tumor is now held firmly against the abdominal opening by pressure from the assistant's hands from above and behind, which is kept up until the sac is entirely emptied. In this way the sac is kept in close contact with the edges of the wound, filling it entirely, so that no leakages of the contents of the sac can find their way back into the abdominal cavity. A large trochar, to which a rubber tube is attached, is plunged into the sac and the contents allowed to flow into a proper receptacle. Allow the contents to flow out slowly. As the tension of the sac wall diminishes, pressure from behind brings it through the wound, so that it can easily be seized with a pair of Neleuton forceps and drawn out through the opening. As more and more of the sac comes out, there come into view different adhesions. Here, for instance, is a fold of omentum firmly adherent to the sac wall. It is secured by transfixion with a needle armed with a double ligature and tied in two sections; the ends of the ligatures are cut short. The omentum is cut through close to the tumor with the scissors. The cut surface is carefully examined to ascertain that the vessels are perfectly secured. If found satisfactory the stump is dropped into the abdominal cavity; if not, it is tied again. A sponge is placed under the omentum before division, to prevent any blood from entering the peritoneal cavity. Soft and recent adhesions are pressed off the surface of the tumor by means of a sponge. Vascular and old adhesions should always be ligated in two places and cut between them. And now, by a rather free pull, I have succeeded in forcing through the abdominal wound the large mass which was felt through the abdominal wall, and I find it to be an aggregation of multitudes of small cysts, rather unusual in its situation in being at the top of the

tumor. Usually such accumulations are found near the pelvic portion of the tumor. The entire mass is now delivered, bringing the pedicle in plain view. It is made up of the expanded broad ligament and the Fallopian tube, much enlarged, running along its free margin over the surface of the tumor, and here we meet with a complication which must be handled with great care. A fold of the small intestine is firmly adherent for a distance of 2 inches along the edge of the pedicle. The tissues of the broad ligament, one-half inch away from the surface of the intestine, is transfixed with a needle armed with a double ligature, tied in halves, and the intestine cut away from its adhesion. The pedicle is now grasped in these long forceps and the tumor cut away.

The next point is to secure the pedicle. It is transfixed through its middle, selecting a non-vascular point, with a rather blunt needle armed with a double ligature of strong silk. The needle is detached, the threads are crossed, drawn around the halves of the pedicle and tied tightly, always removing the forceps before the knot is fastened, to be sure that the vessels are controlled by the ligatures. If all is satisfactory, the ends of the ligatures are cut short and the pedicle is dropped into the abdominal cavity, remembering never to pull upon the ends of the ligatures after they are tied, for fear of loosening their hold.

Now the abdominal cavity is to be cleansed thoroughly of blood and anything else that may have collected. The intestines are held out of the cul-de-sac of Douglas. These small sponges, fastened to handles, are used to remove thoroughly any discharge that may have gravitated into it. We are now ready to close the abdominal wound as soon as the omentum is pulled down over the surface of the intestines. A large flat sponge is introduced into the abdominal wound to protect the intestines and catch the blood coming from the needle punctures. The sutures for closing the abdominal wound are passed through the skin about one-half inch from the edge of the wound and include all the tissues of the abdomen together with the peritoneum. About three sutures for every inch in length of the wound are introduced in this manner. Now a very important duty, and one never to be neglected, is to be performed, and that is to account for all the sponges that have been used during the operation. The flat sponge is now removed and all the sutures tied, being sure to perfectly approximate the edges of the skin, so as to provide for early and secure healing and thus avoid, as far as possible, the dangers of the occurrence of ventral hernia. The wound is dressed dry with iodoform, iodoform gauze, borated cotton and a firm abdominal bandage. The patient is put into a bed warmed with bottles of hot water, the limbs are flexed over a pillow, and the shoulders are raised to relax the abdominal walls. The arti-

ficial heat is kept about the patient until reaction is fully established. No medicine of any kind is administered unless opium is required to relieve severe pain. I think this is best done by rectal injections of 30 drops of deodorized tincture as often as is necessary to control the pain. No food whatever is given for twenty-four hours. If vomiting is present, it is usually readily controlled by giving teaspoonfuls of very hot water. The bowels are moved on the third or fourth day by giving teaspoonful doses of epsom salts every four hours until the result is obtained.

Unless the temperature rises to  $102^{\circ}$  F., accompanied with other symptoms of trouble, the patient will not be disturbed in any way except as mentioned until the seventh day, when she will be brought before you and the stitches removed.

About the only preparation I make of my patients—and it is absolute with me—is to have the patient quiet for three days before the operation, on liquid diet, and to have the bowels thoroughly and effectually emptied of their contents by proper cathartic medicines. Twenty-four hours before the operation the patient has a general bath and a large  $\frac{1}{1000}$  corrosive sublimate douche, followed by a large hot water douche to disinfect the vagina. The abdomen is thoroughly scrubbed and shaved, and an antiseptic dressing is applied, which is left on until the time of the operation. Five grains of quinine with one-fourth grain of morphia are given by mouth one-half hour before operation.

Without accident this lady will not be confined to her bed more than three weeks, and if all goes well she will be able to return to her home by the end of this time. A peer of the English government, during the ceremonies incidental to the laying of the corner-stone of a hospital, a few years ago, made the statement that Sir Spencer Welis had added 20,000 years to women's lives by the performance of such operations.

Notwithstanding the fact that the great majority of patients subjected to laparotomy for ovarian cysts when properly cared for, recover, still when asked if there is any danger attending the operation, be honest enough to say that there is danger.<sup>1</sup>

*Case 3.*—Miss E. A., Chicago, age 32, American, musician, general health good. This patient presents herself to us with a small painful tumor as large as a bean, on the back of the hand, between the second and third metacarpal bones. It has developed within the last six months, after prolonged piano practice.

It is a neuroma, and requires removal. The lady bravely consents thereto without taking an anæsthetic. It is exposed by a short incision directly over it, picked up with a pair of forceps and dissected away. Two catgut sutures, iodo-

form, iodoform gauze and borated cotton dressing complete the operation.<sup>2</sup>

*Case 4.*—J. C. H., Stonington, Ill., age 48, American, farmer. Family history good, patient well until he entered army at age of 20. This patient has had slowly but constantly increasing symptoms of locomotor ataxia, probably caused by exposure during three years' service in the war.

But he appears before us to-day for relief from disabling disease of the right knee-joint, which you can plainly see is very much enlarged and misshapen. Fourteen months ago he first noticed an unusual snapping and grinding in the knee during motion. There came on swelling of the knee and of the leg below as far as the ankle. The swelling of the leg gradually subsided, but the knee remained swollen and its distortion gradually increased, until now an examination shows it to be completely disorganized, movable in all directions, the ligaments apparently destroyed and every motion made in it accompanied with harsh, rough grating. It is also filled with fluid, which upon aspiration is shown to be reddish serum. He has had amazingly little pain in the joint itself, when one considers the amount of apparent destructive changes that have taken place. Yet he has complained, and does complain, of severe shooting pain throughout the leg, and especially in the upper one-third of the tibia, which you can plainly notice is much enlarged. The shooting pains spoken of are common to and characteristic of this general disease, for I take this to be clearly a case of Charcot's disease of the joint, a condition not infrequently present as a complication of tabes dorsalis. It is so named because Professor Charcot, of Paris, was the first one to thoroughly describe it. The most noticeable peculiarity about the disease is well illustrated in this case, in which these most destructive changes have taken place without correspondingly severe manifestation of their progress.

Believing the patient will be best relieved of his trouble by an amputation of the thigh through the middle, we will proceed to do that operation.

The limb was removed by forming the ordinary anterior and posterior flaps by transfixion. No antiseptic fluids or washes of any kind were used on the stump; it was dressed with dry dressing, iodoform, iodoform gauze, borated cotton. The thigh had been rendered thoroughly aseptic before the operation.

The joint was opened and displayed to the class; it displayed the characteristic appearance of a Charcot's joint—the fluid sanguineous, the articular ends of bones enlarged, that of the tibia being worn off as by a grindstone and much hardened.<sup>3</sup>

<sup>1</sup> The wound is dressed on the eighth day and found perfectly healed. The pain has disappeared.

<sup>2</sup> The patient was brought in on the eighth day and showed to the class for first dressing. The wound had healed throughout by first intention.

<sup>3</sup> The stitches were removed on eighth day, union throughout. Temperature has not reached  $100^{\circ}$  F., has felt comfortable, can move about in bed, and sat up on fifteenth day.

*Case 5.*—Miss R. Chicago, æt. 25, American, flower girl. General condition fair, family history good. This patient is suffering from persistent and apparently uncontrollable pain following excision of the knee for tubercular disease. The excision has been a perfect one and the recovery is complete, but the patient is prevented from following her avocation and demands an amputation of the thigh, in spite of advice and protests of physicians and friends.

Two operations for the purpose of dissecting out nerve fibres compressed in the cicatrices left after the excision have been made, but these failed to give relief. The amputation will be made as low down on the thigh as possible by means of two skin flaps formed from without inwards and a circular division of the muscles just above their base. You notice that in dissecting up these flaps I am very careful to take up with the skin the full thickness of the superficial fascia beneath it. This is to provide for the flap's nourishment. The blade of the knife is always made to cut transversely to the limb's axis in severing the tissues. In all flap amputations the sum of the lengths of the two flaps should be about 2 inches longer than the full diameter of the limb at the seat of section of the bone, so that they may be free from any tension or harmful retraction, and also to avoid a conical stump when the healing is complete. The amputation was made as described and dressed as the previous one. You will notice that in both amputations the flaps are approximated by continuous catgut sutures which bring the skin edges together neatly and accurately throughout the entire length of the wound.<sup>4</sup>

*Case 6.*—J. F., Chicago, æt. 3 years, poor health. This child comes before you with a well marked swelling of the dorsal surface of the hand principally covering the head of the metacarpal bone of the middle finger. The trouble is uncertain in character. An incision over the surface of it demonstrates it to be a tubercular abscess, connected with tubercular degeneration of the head of this metacarpal bone. I will proceed to curette the cavity freely and remove the particles of dead bone. It will now be washed clean and packed with iodoform gauze and the wound covered with borated cotton.\*

*Case 7.*—Otto B., Missouri, æt. 15. This is a well-marked case of talipes equinus following infantile paralysis. There evidently has been an arrest of development in the right lower extremity of this patient, for it is much smaller in every way than the other one. The activity of the muscles has been restored, but in all probability his attempt to equalize the length of the limbs has been an element in the extreme contraction of the muscles attached to the tendo Achilles. All we

can do in this case is to divide this tendon and place the foot at a right angle with the leg and fix it in that position by a plaster of Paris cast. This brings the side of the foot of this diseased leg two or three inches above the ground when he stands erect on the sound leg, so he will be compelled to wear a shoe sufficiently elevated to make the limbs of equal length. This will enable him to walk with much more ease and comfort.

In dividing the tendo Achilles introduce the tenotome through the skin an inch away from the edge of the tendon; pass it subcutaneously either above or below the tendon while it is relaxed; turn the cutting edge toward the tendon rendered tense by forcible flexion of the foot. A slight pressure upon the knife will divide the tendon readily. It is well to choose the narrowest part of the tendon for its division. It is important to avoid wounding the posterior tibial artery. All of this is done and you now see the foot comes easily to a right angle with the leg, and you notice as well the deep depression in the course of the tendo Achilles caused by the separation of the divided ends. This space will be filled up with connective tissue and the function of the tendon restored.<sup>5</sup>

*Case 8.*—Mrs. Catherine M., Chicago, æt. 52, Irish, housewife, general appearance good. This case presents for inspection an angry-looking growth about the size of a bean, situated over the triangular cartilage of the left side of the nose. The patient tells us it is growing larger and becoming more irritable. I deem it to be an old wart taking upon itself epitheliomatous degeneration. Its removal is advised and consented to. The tumor is included in an elliptical incision far enough away to be in healthy skin. Its depth extends entirely through the thickness of the skin.

The edges of the resulting wound are easily approximated by two sutures, making a linear scar entailing no deformity, dressed with iodoform gauze.<sup>6</sup>

*Case 9.*—A. T. J., Chicago, American, drug clerk. This young man presents himself with a swelling as large as a good-sized potato and very similar in shape, on the posterior surface of the upper part of the right leg. The growth evidently pushes all the muscles of the calf in front of it. It is hard and irregular to the touch where it can be felt underneath the edge of the muscles. It causes no pain or inconvenience except from its size. It evidently is an outgrowth, bony in character, from the posterior surface of the upper part of the tibia. It belongs to the class of innocent tumors and is technically called an exostosis. I cannot advise any operative procedure so long as it is harmless in its manifestation. Should it at any time become a source of trouble through in-

<sup>4</sup> On the eighth day the patient was brought before the class for the first dressing. Wound united, patient had been perfectly normal and free from pain ever since operation.

\* Wound perfectly healed at end of five weeks.

<sup>5</sup> At end of two weeks cast removed, position perfect. Cast re-applied, to be left on for three months.

<sup>6</sup> On eighth day wound is united throughout.

creased enlargement I think it can be safely removed.

*Case 10.*—Mr. Wm. V., Chicago, æt. 47, English. This patient shows his hand with the little and ring fingers flexed into the palm of the hand and fixed in that position. When I attempt to extend them and examine the palm of the hand beneath them I feel a very readily a distinct band rise up under the palmar skin. This band is rendered very tense at every attempt at extension of the fingers. On either side of these bands are to be seen several small dimple-like depressions in the skin. This trouble is technically termed a case of Dupuytren's contracted fingers, and is a deformity resulting from injury to the fascia of the hand which produces a contraction of the connective tissue in and about the deep fascia. Its tendency to contract flexed the fingers and holds them immovable in this abnormal position.

The flexor tendons are not primarily concerned. The trouble was named after Prof. Dupuytren because he was the first to accurately describe the pathological conditions.

To overcome this deformity we introduce the tenotome and divide all of these resisting bands met with in succession as the fingers are forcibly extended. This is all done subcutaneously, as you plainly see; the hand in the first place having been rendered positively aseptic. The wounds are dressed with iodoform and iodoform gauze and the fingers bandaged in an extended position to a well padded splint.<sup>7</sup>

*Case 11.*—J. W., Chicago, age 30, Scotchman, machinist, generally healthy, well nourished. On examination we find that this man has a mass taking the place of the left epididymis of the same size and shape and of a cartilaginous hardness. Cases of this character and presenting this special feeling have in my experience proven to be tubercular. Based upon that belief this affection, however slight and simple it may seem to be, is of serious import to the patient. While it is present it is a constant source of danger from possible general tubercular infection. The only reasonable treatment to advise or pursue is total extirpation of the diseased organ. The patient does not consent to any such interference, and I did not expect him to, still I am quite well convinced that it is the safest procedure to adopt in this case, and is my duty to warn him of the risks he runs with this centre of disease in his system.

As he will not consent to the operation suggested, we will prescribe such medicines as are supposed to have a beneficial influence on this disease. Bichloride of mercury of  $\frac{1}{8}$  a grain, three times a day.

*Case 12-17.*—The six patients now shown to

<sup>7</sup> Two weeks after the above operation the little finger is in the extended position and movable. In the ring finger full extension is still not possible on account of a few more bands, which will shortly be divided.

you are all illustrations of the enlargement of the thyroid gland, technically termed goitre, or bronchocele or struma.

The points in diagnosis are, first, its position in front of the neck; second, its shape, spread eagle, a small body in the centre and large wings on either side; third, it rises and falls with each act of deglutition, as I illustrate with this patient, because it is normally fastened to the trachea.

The growth may be unilateral, bilateral, or central, according as one or both lobes or the isthmus, or all three are the site of the manifestation of the disease. The growth may be cystic, single, or multilocular, adenomatous, vascular, or fibrous; or the tumor may be a sarcoma or a carcinoma of the thyroid gland. Again, we are often called upon to treat cases of enlargement of the thyroid gland associated with bulging of the eyeballs and distressing pulsation of the large arteries of the neck. Such cases are termed exophthalmic goitres.

The cases before us are all examples of cystic or adenomatous enlargement of the thyroid. We have fallen into the habit of treating these cases by the weekly injection into the substance of the gland of a drachm of the 5 per cent. sol. of carbolic acid in water. This treatment is followed by a rapid diminution in size in many cases, and a perceptible improvement in all who have regularly returned. I have added to this treatment the use of 5 drop doses of Donovan's sol. three times a day, with what benefit I am not yet able to state.

*Case 18.*—This patient returns to show the result after removal of two-thirds of the lower lip for epithelioma. The wound is perfectly healed and the deformity of the mouth very slight, when you consider how much tissue was removed.

## MEDICAL PROGRESS.

ETIOLOGY AND TREATMENT OF OBSTINATE VOMITING OF PREGNACY.—In a paper read before the Académie de Médecine by M. GUÉNOR, the author summarizes his conclusions as follows: The idea of combating obstinate vomiting of pregnancy with a single remedy or mode of practice seems to be quite erroneous, as its uselessness has been proved by experience. No one therapeutical agent has been shown to exercise a constant curative effect. This is as we should expect inasmuch as the obstinate vomiting of pregnancy is dependent upon a variety of causes arising from three organs or systems, first, the uterus, which at once is the very focus of pregnancy and a source of special excitement affecting the other organs. Second, the nervous system, (spinal and ganglionic) which by the aid of its

reflex power transmits the excitement to other organs. Third, the stomach, which is the seat and agent of the principal symptoms, and especially susceptible to uterine influences.

In order to treat these cases with assured success it is necessary to have recourse to a complex treatment which is directed to all three of the sources of the disorder, and hence there are three fundamental indications to be considered; these are, first, to reduce the morbid or abnormal uterine excitement by remedying the various pathological conditions which produce it. For this purpose belladonna, cocaine, morphine, vaginal injections, or topical application, the Gariel pessary, elevation of the hips with a sloping decubitus of the body, cauterization and even artificial dilation of the cervix are the resources which may be most advantageously employed, according to the necessities of each case. Second, to diminish the activity or suppress the exaggeration of reflexes, a result which may be secured by the use of chloral with the bromides, by the application of cold to the spine by means of ice or the ether spray, by moral influences, by descending galvanic currents, etc. Third, to combat the intolerance of the stomach by treating its various disorders and soothing its irritability by means of the following agents: Diet, almost absolute and rigorously enforced; the avoidance of all acid drinks, wine, orange and grape juice, etc.; the use of mineral waters, such as Vals or Vichy, and ice in very small quantities; blisters at the pit of the stomach; ether spray in the same region; the occasional use of laxatives or substances calculated to regulate the functions of the intestines.

Finally, to secure the full effect of such treatment, it is particularly essential to lessen the work of the stomach as much as possible, and with this in view, rectal hypodermic and endermic medication should be made available as far as possible.—*Bul. de l'Acad. de Méd.*

**VARIATIONS OF BODILY WEIGHT IN TYPHOID FEVER.**—Dr. L. H. COHIN, of Paris, has made valuable observations in the Cochin Hospital regarding the daily variations in the weight of typhoid fever patients. He found that the loss of weight per diem amounts to from six ounces to one pound. In convalescence the mean of daily gain was about nine ounces. The maximum of loss of weight corresponded to the end of the second week, or the beginning of the third. The investigator also established the fact that the patient lives at the expense of his own substance. His general conclusions are as follows:

1. Typhoid fever presents two distinct periods, one of loss and one of gain; certain accidental causes may modify them, but cannot effect their general character.

2. The daily loss is due to febrile combustion chiefly, and but little to abstinence.

3. The daily loss varies with individuals.

4. The losses in nitrogen and weight are almost parallel with the march of the temperature, without always following it exactly.

5. The study of the weight chart may aid in prognosis, a continual rise in the weight being a sign of convalescence.

6. The complications of the disease augment the loss of weight.

6. The study of the loss of weight enables the physician to determine with precision the action of nutritive substances in fevers.

8. The loss of weight in a typhoid patient takes place each day in a uniform manner.—*Boston Med. and Surg. Journ.*, Sept. 12, 1889.

**TONSILLITIS.**—Dr. G. F. BONCSEIN, of Baltimore, draws attention to the frequency of tonsillitis in children, quoting Dr. Chappel's report of 2,000 children examined in New York, among whom 13½ per cent. were found with enlarged tonsils. Regarding treatment, Dr. Boncsein advises *écrasement* with the electro-caustic snare or igni-puncture, with the sharp pointed electrode, the latter method having the following advantages: 1. It is more easily managed, and 2, it causes a great deal less pain, and none after the preliminary application of a 4 per cent. solution of cocaine. The application is simple: under red heat the electrode is plunged into the tonsil to the depth of a quarter of an inch, held there for a moment and then withdrawn. A second and third puncture may be made at the same sitting; four to seven days must elapse between sittings, and from three to five sittings will be necessary to contract the tonsil. The after-treatment consists in the use of alkaline gargles. The only other local treatment used by the writer consists of poultices to the outside of the throat, inhalations of steam and incision when there is an abscess. As for constitutional treatment, he has employed salicylate of sodium with benefit in rheumatic cases, and benzoate of sodium to control the febrile element of the disease. He has no faith, however, in the curative or abortive power of any remedy in acute tonsillitis, which he believes to be a specific disease running an average course of three and one-half days in spite of all treatment.—*American Journ. Med. Sciences*.

**TINCTURE OF EUPHRASIA IN ACUTE CORYZA.**—Dr. G. M. GARLAND strongly recommends the tincture of euphrasia in the treatment of ordinary colds. He finds that if given in the early stages the coryza is usually aborted, but that in advanced stages its effects are much less marked. The dose for an adult is ten drops every two or three hours. In infants and children the drug should be given in smaller doses well diluted.—*Boston Med. and Surg. Journal*.

SATURDAY, DECEMBER 7, 1889.

MILK AS A VEHICLE OF TUBERCULAR  
INFECTION.

At the meeting of the Association of American Physicians at Washington, Sept. 20, 1889. Dr. HAROLD C. ERNST, of Boston, read an important paper on the question of the safety of using the milk of tuberculous cows for food. Although the possibility of contracting tuberculosis from this source has already been recognized, the danger has been generally supposed to be confined to the milk of cows whose udders were invaded by the disease. Dr. Ernst gives very strong reasons for thinking that there is not even this degree of security. His investigations were made under the auspices of the Massachusetts Society for the Promotion of Agriculture upon thirty-six tuberculous cows, which presented no evidence of disease of the mammary glands. The milk was examined for the tubercle bacillus, inoculations of the milk and cream were made upon rabbits and guinea pigs, calves and pigs were fed upon the milk, and, finally, thorough post mortem examinations were made on the animals which gave positive results. From the account given of the methods employed, the examinations would seem to have been made with great care, and with all due precautions against all possible sources of error. The results obtained were decidedly startling.

Tubercle bacilli were found in the milk and cream of ten of the thirty-six cows examined. Out of eighty-seven animals inoculated with

milk and cream from fourteen cows, seventeen were infected from seven cows. Five out of twelve calves and two out of five pigs fed with milk from the diseased cows became tuberculous. Finally, tuberculosis of the udder was not evident to the naked eye in any cow examined, and in only one case was a single tubercle found by the microscope.

The bearing of these facts is obvious. If the danger of infection is anything like as great as would appear, the freedom of milk from the customary adulterations is a matter of trifling importance in comparison with the soundness of animals that furnish it. All the tuberculous cattle should be promptly slaughtered, both in the interest of the owners and of those whose health is endangered by them. In case of any doubt as to the quality of the milk supply, it would seem to be the part of prudence to guard against the possibility of danger from these sources by boiling the milk.

It cannot be claimed that KOCH's discovery has contributed very much, thus far, to the therapeutics of phthisis, and it may be doubted if, rightly understood, it gives much encouragement to the search for a specific. It is not, perhaps, impossible that a poison for the bacillus may be found which will be innocuous to the system, but as a rule, what will kill the weeds will kill the crops. Nevertheless, the benefits of increased knowledge are manifest, even now, and it may not be over sanguine to hope that the time will come when, like leprosy and the plague, tuberculosis will be practically extinct in civilized lands.

RELATION OF ALCOHOL TO INSANITY.

The dependence of a large percentage of crime upon the abuse of alcohol is a matter of everyday observation, and the relation of cause and effect is no longer seriously questioned. The rôle that alcohol plays in the causation of insanity is for many reasons a much more obscure and difficult problem. The determination of the causal factors in any given case of mental alienation, even in so-called puerperal cases, is at best and necessarily but a summation of the probabilities. The facts upon which the decision is to rest are difficult to obtain and, when elicited, usually point to a number of predisposing conditions and a pleurality of possible exciting causes. In American

communities the difficulties are amplified by the transition state of our populace. What to-day are hamlets, in a decade are towns, and in a score of years may be cities. All habits and modes of living may thus, for any individual, be widely varied within a short period, and who can estimate its influence upon the character and nervous organization. Besides, our population is heterogeneous in a high degree. The higher proportion of insanity among foreign born, as compared with those of native birth, influences averages for the worse and makes statistics misleading and of doubtful value. An opinion is current that insanity is greatly on the increase in this country, but this is not absolutely to be determined. Many cases such as formerly were cared for by friends or allowed to run at large are now placed in asylums and brought within the limits of statistical returns. The better care, treatment and protection of this unfortunate class has, during the past two decades, notably increased their longevity, so that the average duration of insanity has been lengthened nearly fifty per cent. Moreover, many are now placed under such medical treatment and control as can only be afforded in well-equipped institutions, who in former years would not have been admitted, and whose sanity would never have been questioned. Then the immigrant class, predisposed to a high insane average, are subjected to the toils and privations and hardships of newcomers, to which is added the potent depressing influence of separation from home and friends. From these various sources of error any deductions upon the question in hand derived from observations in this country would have but little reliability.

It is, therefore, with interest that we read the proceedings of the Third International Congress for the Study of Alcoholism, held in Paris last August. England, Holland, Belgium, Switzerland and some other countries were fairly represented, but on the whole the affair was distinctly French, and the observations and conclusions adopted pertain to France in particular, though applicable to other European States.

It was announced, and the statement was supported by Government reports, that insanity had increased nearly one-half in the past twenty years. The pertinent question is in regard to the cause of this appalling increase. In France, for instance, there is no considerable movement of

population, not even by natural growth, the conditions of life and society are crystallized in the mould of tradition and custom, their hospital facilities are only enlarged upon urgent demand, and the care of the insane is about what it was twenty years ago, speaking from the standpoint of protection, supervision and asylum quarters. Their people are in a high measure of one nationality, for, outside of Paris, resident foreigners are comparatively rare. While then the population and general conditions have remained nearly stationary, insanity has wonderfully multiplied.

It was also shown, and the showing is again based on Government reports which are for this particular absolutely reliable, that the consumption of alcohol for drinking purposes had increased in almost the same ratio during this period of twenty years. These two facts taken together, suggestive as they are, would not justify hasty generalization. It may be urged that the tendency of insanity to increase from hereditary causes might account for the enlarged percentage of this unfortunate class. An increment from this source must undoubtedly be admitted, but a tendency to barrenness among those of well-marked hereditary neurotic taint has long been observed and acts as a fortunate though partial offset. Probably a history of the severer neuroses in antecedents and near relatives is obtained in cases of insanity as frequently as a distinct hereditary insane trace, and the question as to the dependence upon alcoholism of these diseases which seem to entail a liability to insanity is raised. Many authoritative writers and prudent observers consider such a relation to often exist.

A strong light is thrown on the situation by the fact that the increase noted in France is almost entirely made up by cases of alcoholism and general paralysis, the ordinary forms of insanity retaining approximately their former ratio. The same thing is true in a greater measure in Holland, where, of late years, alcohol distilled from potatoes has come into general use, the effect of which is said to be particularly harmful as compared with alcohol otherwise derived. It probably is in accord with the statements of a majority of trustworthy writers to attribute general paralysis to alcohol or the vices which are correlated with its excessive use. DR. GARNIER, in a paper read before the International Congress of Mental Medicine held in Paris about the same time, goes to

the extreme of attributing general paralysis solely to the abuse of alcohol, a position strongly combated in the debate which followed and which is not altogether tenable unless the widest latitude for indirect causation is granted.

The members of the Congress first mentioned manifested a marked unanimity of opinion in regard to the relation of insanity to the consumption of alcohol, and the following resolutions or views were adopted:

1. The increased consumption of alcohol is one of the principal causes of the development of crime and insanity.

2. A diminution in the number of drinking places being one of the means of reducing the consumption of alcohol, this Congress is of the opinion that Governments should take measures to restrict the number of dramshops.

Opinions were also expressed that crimes committed during the delirium of inebriety should not entail full responsibility but, on the other hand, that society should be protected against such drunkards by their being subject to sequestration in suitable retreats.

Whatever may be one's personal opinion, the expression of the above views, coming as they do from an intelligent body of men, must carry emphatic weight. It must be borne in mind that the members of this Congress probably never contemplated prohibitory legislation, that they live in countries where in some form alcohol is, as a rule, a part of the dietary, that in no way can the cry of fanaticism be raised, and that, in all probability, the great majority of them use alcoholics more or less themselves. This lends added importance to their action.

It is probably well within the limits of facts to consider the abuse of alcohol as not only capable of causing insanity, but as being a frequent cause of this the most distressing and wide-reaching calamity that can befall an individual or a family, and which imposes a heavy burden of tax and responsibility upon the community at large.

**AN ESSENTIALLY WOMAN'S HOSPITAL.**—A hospital devoted to diseases of women and under the patronage of the Princess of Wales is to be established in England. The special feature of the institution is that all services to the patients, both professional and otherwise, are to be rendered by women.

#### LOCAL MEDICAL ORGANIZATIONS.

With a commonwealth that has within a century developed from thirteen States to forty-two; with a population increased from three to over sixty millions; in the midst of a people keen of perception and intensely practical in their estimates; with whom, in every department of learning, from that of the public school to the University, a high order of culture is possible, and where the varied industries are so well rewarded that ample means are at command, it is not singular that men in all the walks of life are keenly alive to their personal interests, and studiously intent as to the best methods of accomplishing desired results. Thus, our very industries are prolific of invention, and little heed is given to precedents. Every department of education is feeling a like strong impulse to the development of better and better methods of instruction, and the advances that have been made in educational methods within the last few years are simply marvelous. This impulse is at last taking strong hold upon the medical profession. Medical men are more and more dissatisfied, as well they may be, with the present professional status. The demand for better methods of teaching; for men better trained in preliminary studies; and for a much higher standard, to which they shall attain, before entering the medical profession—these are the prominent themes that point the pens of our best writers, and command the considerate judgment of our best thinkers.

The great problem which now confronts us, and which during the next twenty-five years must have its practical solution is this: how so to bring the standard of medicine from its present low state to that high plane, and the masses of medical men to that degree of culture where medical science shall find legitimate expression, and the art of healing render its best services to men, creating positions which men may hold as posts of honor, and up to which quackery and charlatanism may not climb. This is the requirement of the hour and of this age.

Science and art, and invention, are laying their contributions at the feet of the medical profession with a demand to be utilized in the interest of mankind. The dawn of a new century is upon us. Already the outlines of grand possibilities can be discerned. If at the present hour medical men shall prove themselves unequal to

their opportunities, then let there be no murmuring though the honors of our profession continue to trail in the dust, while charlatans run riot in their misrepresentations of medical science. But this shall not be, for the men are already upon the stage who will do valiant work in the saving of our profession from such humiliation.

There needs at this stage to be set forth not only a clear statement of the work to be done, such as shall command the hearty approval of a united profession, but secondly, that the means for successful accomplishment shall be used with utmost discretion. Whatever efforts the profession shall put forth for medical advancement in America, those efforts must be in full accord with the genius of American institutions. It is clearly manifest that legislation, and legislation only, can accomplish the desired result. With us that power of legislation vests with the people, and it is their voice which must first be heard before results can follow. For more than a century we have been accustomed to trust this people, and we can trust them now. Assure them fully as to what their best interests require, and needed legislation will quickly follow. We come then to the significant fact, that our present greatest need is that of medical men, who by ability and culture, and fidelity to their profession, shall be able to rightly educate the masses as to their common good, and so develop a healthful public sentiment. In this great work it is true that every able and highly cultured medical man will be needed as a standard bearer, but it is equally true that the burden of this work must fall upon the rank and file of our profession, as they shall mingle with the masses.

In the accomplishment of results so important men must act with intelligence and in harmony. Hence, the imperative need of efficient local medical organizations in every hamlet, town, city and county of every State in the Union. Each organization has a right to command the best of talent and the best of culture that the profession of that locality can contribute, and the duty of every medical man is only measured by his ability to rightly influence the body politic. Here lies the power that at last shall move the State. The vitality of local societies will determine the power and efficiency of State organizations. The delegations from the local societies will give to these the impetus of personal convic-

tions, and State societies will only be what local societies shall choose to make them. And in this general work of local organization our medical journals can wield their power with great efficiency for good, and serving best the needs of the profession they shall serve themselves a well.

#### THE MEDICO-LEGAL RELATIONS OF ANTI-SEPTIC SURGERY.

Shall Listerism be accepted as a criterion of the medico-legal responsibility of the operating surgeon? There are those who hold pronounced views respecting the status of antiseptic surgery, who virtually say that the surgeon who has not adopted it is not doing his best for his clients, and who seemingly would not find it difficult to testify against their a-Listerian brethren if or when called upon to give expert testimony in a suit for malpractice on this ground of the nonuse of antiseptics.

We shall not be surprised if some acute legal mind might seize upon this proposition and make trouble in the camp of surgery—or try to do so. That he shall be able to make good his case may well be doubted, or that the courts will fall into practice of measuring all surgery up to the enthusiastic views of some Listerians must be doubtful, also. However proudly the asepticicians may feel, or however roundly they may boast in their lectures or addresses, there remains yet the time-honored dictum of generations of medico-legal experience: the surgeon “undertakes to employ a fair, reasonable and competent degree of skill.”

The surgeon does not contract to furnish the highest possible degree of skill, no more than the physician contracts to make a perfect cure. He is not required to subscribe to any particular theory of treatment any more than he is expected to be the disciple of any particular school. He is to be true to himself and to exercise his attainments and powers to the extent of his ability; he is the practical exponent of the argument of POLONIUS when he declares to LAERTES that with self-truth he could not be false to any man. And a century of judges have ruled that way and have saved a world of loss and trouble to assailed practitioners. Wherever that line of judgment is departed from, if only temporarily, there it is likely that an epidemic of malpractice suits, under-

taken on speculation, will spring up. However enthusiasts may wonder at the laws delay in accepting their favored theory as a ground for legal decision, it is best to be lenient with that conservative trait in the legal character, for it has served the medical profession many a good turn in days gone by, and may do the same again whenever malpractice suits shall become fashionable. Like some fruits, medico-legal postulates take a long time to mature.

---

#### EDITORIAL NOTES.

##### HOME.

**RECTAL TREATMENT FOR THE VERY POOR.**—The New York Post-Graduate Hospital will hereafter have a special clinic for diseases of the rectum.

Dr. Charles B. Kelsey has been appointed to have charge of this clinic. He invites especially those who are quite without the ability to pay any medical fee, a deserving class, not infrequently who suffer from prolonged neglect. The more necessitous the case is, oftentimes, the greater the neglect, in this type of disease.

**UNIVERSITY OF PENNSYLVANIA'S DEPARTMENT OF PHYSICAL EDUCATION.**—The physical culture proffered, at the University of Pennsylvania, under the direction of Dr. A. H. P. Leuf, to the professional students, as well as the academic, is accepted more and more every year. When the professionals go into training for any of the athletic contests, they have the gymnasium fee remitted to them. In "The University," October, 1889, Dr. Leuf has an article on what he regards as some of the existing defects in college physical training, and their remedy. A winter-house for practice, to cost \$5,000, is a pressing need, and he is actively engaged in the raising of funds for its construction.

##### FOREIGN.

**SANITATION IN FRANCE.**—A decree issued June 3, 1889, authorizes the city of Angoulême to negotiate a loan for the purpose of defraying the expense of improving the water supply of that city. The city of Alençon is also authorized to effect the same improvements. Beaune, (Côte d'Or) is authorized to contract a loan to pay for an improved water supply and for the construction of sewers. The cities of Sedan and Nice are

authorized to improve the drainage by contracting a loan to defray expenses. Reims and Poitiers have followed the example set them by the French capital as regards the sewage system and subsequent utilization in agriculture.

**TRANSMISSION OF DISEASE BY BRUSHES AND DENTAL INSTRUMENTS.**—A discussion recently took place at the Conseil d'Hygiène concerning the transmission of certain diseases by hairdressers and dentists, the brushes and instruments being used in common for all their clients. M. Lancereaux wished to have stringent measures enforced, and cited a case of phthisis which Dr. Cochrane, an American dentist, alleged was transmitted by a dentist's instrument. M. Du-jardin-Beaumetz and others declared that there were great difficulties in the way, but recommended great care in schools and public institutions.

**VACCINATION IN JAPAN.**—Vaccination, according to the *Medical News*, has been obligatory for some years in Japan, and every infant is required by the police to be vaccinated. The value of the procedure is, however, well recognized by the people themselves, and the government hospitals in every town are always thronged with applicants on the weekly "vaccination day." In 1886 there were 1,531 vaccinations to each 10,000 inhabitants.

**INFECTIOUS DISEASES IN THE THAMES.**—The *British Medical Journal* says, that Dr. W. Collingridge, Medical Officer of Health for the Port of London, in his half-yearly report, strongly recommends the erection of a small isolated building at the Port Sanitary Hospital for the accommodation of small-pox patients, who are at present treated in the same building as those suffering from other diseases. Referring to the dangerous position of training ships, which are without means of isolating infectious diseases in cases of outbreak, he recommends the establishment of a small isolated hospital for each ship. Reference was made to an outbreak of chicken-pox among the crew of a vessel after her arrival in London, three weeks after the first patient had apparently recovered, in consequence of which application was made to the Local Government Board to add chicken-pox to the list of disorders regarding which the Port Sanitary Committee have power to make regulations.

## TOPICS OF THE WEEK.

## LISTER'S NEW ANTISEPTIC DRESSING.

In an address delivered before the Medical Society of London on November 4 by SIR JOSEPH LISTER, Bart., F.R.S., Professor of Clinical Surgery in King's College Hospital, he gives in a most interesting manner the details of a series of experiments extended through several years, conducted with a view to determine what substances are most available for antiseptic dressings, and also to discover the most approved methods of their application. In this address he brings to the attention of the profession the double salt of the cyanide of zinc and mercury, as one having special claims to favor both as a germicide and for its inhibitory power as well. By the agency of starch the double cyanide becomes adherent to gauze and may be used with facility. Reviewing his experiences with this new dressing he says: "Such being the case I feel not only permitted but bound to bring this material under the notice of my professional brethren. As to the composition of this so-called double salt, it is for the present uncertain. This much is already established: that the cyanide of mercury is in very much smaller proportion to the cyanide of zinc than Watts' *Chemistry* would lead us to expect the double salt would give. But what the precise composition of the salt is we do not yet know. I am having it investigated by the Pharmaceutical Society, who have kindly undertaken the work."

Prof. Lister concluded his admirable address with the following words: "The sketch which I have given you of this investigation, though it has, I fear, wearied you conveys but a small idea of the toil it has involved. There are those who still believe that the use of antiseptic substances in surgical practice is always useless, if not injurious. The germ theory of septic diseases is indeed now happily established incontrovertibly. All now admit that septic mischief in our wounds depends upon the development of microorganisms in them derived from without. But the gentlemen to whom I refer are, more or less logically, disposed to trust everything to the antiseptic powers of human tissues."

"I believe I happened to be the first to direct attention to the antiseptic agency of living structures, and there is perhaps no one who attaches greater importance to it than I do. Without it surgery in former days would have been absolutely impossible. Still, I know too well from experience that it cannot always be trusted, and that the use of antiseptic adjuvants is in the highest degree important. And I have the satisfaction of knowing that there is among you a constantly increasing number who, when they have operated on an unbroken skin, with a fair field around for the application of their dressings, if they see septic inflammation occurring in the wound with its attendant dangers, know that it is their fault or the fault of the antiseptic appliances at their disposal. To those among you who are impressed with this conviction I offer the dressing which I have described as the most satisfactory that I have hitherto met with; and I venture to hope that you will regard it as a not unacceptable addition to your resources."

## THE CAUSES AND PREVENTION OF INFANT MORTALITY.

At the recent meeting of the American Public Health Association in Brooklyn, DR. JEROME WALKER, of New York, presented a paper with the title named above, from which we make the following extended abstract. We only regret that we cannot present the article entire.

It is believed by many that the ratio of infants' deaths to the whole number of deaths in any community is a test of the healthfulness of that community. It has been repeatedly said that the public administration of sanitary measures in any city or town can be judged as to its efficiency by the rate of infant mortality in the city or town in question, and that a decrease in the mortality of infants means more efficient health authorities than hitherto. When I agreed to read a paper before this Association it seemed an easy matter to show that infant mortality has decreased of late years in this country, owing to an increased efficiency of health boards and other sanitary associations; but a study of statistics does not show either that the mortality has decreased in the country at large, or that the efficiency of health boards in general has increased sufficiently to be a strong factor in effecting a decrease. Notwithstanding these conclusions the prevalent high death-rate of infants, *i. e.*, of children during the period of the first dentition, is not a reflection upon sanitary science, for wherever the science and art of preserving health has had a fair chance, infant mortality has been reduced. We may agree with Dr. H. B. Baker, of Michigan, who says: "I have no hesitation in subscribing to the belief that much of the infant mortality could be prevented by thorough and enlightened action by local boards of health in cities and villages;" but we all know that this sort of action will not be taken until, by civil service or otherwise, men best qualified for positions on such boards get them, and will give that personal attention to sanitary details that the mere political doctor will not do.

Sanitary science will not have a fair chance until personal attention of qualified persons to sanitary details can be had, and this cannot be, in some cities, with the meagre appropriations made for the execution of health laws. The outlay for proper sanitary work seems enormous to the taxpayer, but a proportionate result justifies the expenditure. In my opinion the rapid advance that will be made within the next ten years in sanitation, and the training that the people will undergo, will materially lessen infant mortality. As an evidence of this are the following facts: In Brooklyn, in 1878, the population was 531,100. There were 11,075 deaths from all causes. Of these deaths 5,294 were among children under 5 years of age, and 2,943 of children under 1 year. In 1884 the population was 644,526; total number of deaths, 14,116; of children under 5 years of age, 6,271; under 1 year, 3,924. In 1888 the population was 794,682; total number of deaths, 18,061; of these 4,944 were among children under 1 year of age, and 3,075 of children between 1 and 5 years.

To rear a child now-a-days so that it shall have a healthy mind in a healthy body is more difficult, probably, than it was fifty years ago. As wealth increases, poverty increases and the susceptible baby suffers.

Worry, anxiety, insufficient food, over-feeding, insufficient sleep, coddling, exposure, all bring with them dangers to health. Among the causes of sickness which seem to be growing stronger are the over-heating of houses, frequently with air deprived of moisture and laden with gaseous impurities from contact with cracked and over-heated furnace pots, over-feeding with prepared baby foods, sweet crackers and dainties, the relegation of the care of children to nurses, many of them tricky and incompetent, an increased susceptibility to nervous complications and disorders, and artificial feeding instead of natural nursing by the mother. "Why," asked the late Prof. Charles Buckingham, "do American born females make such poor wet-nurses compared with the immigrants from Ireland or Germany? After nearly thirty years of practice I cannot answer the question. That it is a fact, few practitioners in our large towns and cities doubt. . . The consequence of the early failure of the supply of breast milk is the early attempt to fit the stomach for other food. Add to this the parental pride which interferes for the poor pleasure of seeing a toothless child swallow the food of an adult, and you have for the result cholera infantum, dysentery, convulsions, tabes mesenterica; and if, by reason of extra strength, the child passes the first dentition, it is more likely to be cut off during the second, or to become later a dyspeptic or even phthisical. . . The fact has become more and more apparent that large numbers of women cannot nurse their children, and those who are beginning to constitute the exception. Formerly this inability was not so common, occurred only occasionally, and, when partial, did not attract attention."

Take this true statement of Dr. Buckingham in connection with the following extracts from the writings of Drs. Nathan Allen and Elisha Harris, together with the fact that a considerable number of physicians now-a-days advocate, for various reasons, artificial feeding in preference to natural nursing, and we have an important factor in the increase of infant mortality and one which boards of health cannot well reach. "The type of a good nurse," says Dr. Allen, "is a woman with a sound and healthy body evenly balanced in all its parts. There should not be a disproportionate development in any of the organs or systems of the body. Heredity and the mode of living of the average woman produces an excess or deficiency in nervous or muscular force and an undue development of the lymphatic organs. Among the causes are educational pressure, constant excitement, depression of spirits, too much society, hard work, great exhaustion, etc." In 1874 Dr. Harris wrote to a special committee of the Board of Supervisors of Kings County as follows: "The three great private charities in New York city that receive newly born infants and also provide, to some extent, lying-in wards, admit, in the course of the year, about 1,900 newly-born infants. The rate of mortality in the groups of infants whose mothers (however poor or however young) tarry to nurse their offspring has been, during the past four years, just about 14 per cent., while in the hired wet-nurse class the rate of death averages about 27 per cent., and in the strictly foundling and orphan class, that are bottle fed or spoon

fed, the rate is 70 per cent. dead in the first year and 90 per cent. before the end of two years. The causes in general of infant mortality are: First, hereditary, viz: syphilis, scrofula, tuberculosis, excessive nervous irritability, etc.; second, those due to the child's environment, too little or too much care, exposure or over-protection, insufficient or too much food. These causes result in dyspeptic ailments, intestinal disorders, contagious diseases, marasmus, convulsions, capillary bronchitis, pneumonia, etc. While "general debility" is not considered as a separate and distinct affection, the term is a convenient one to use to designate that condition which follows, especially in our cities, many cases of intestinal disease. Whooping-cough, measles, scarlet fever and diphtheria or that is in the child at birth. Muscular and nervous debility are too frequently associated with the ailments of children now-a-days. This being so, there is more need of recuperation in the summer than heretofore.

How to correct the mode of living among the ignorant demands the wisest thought of the wisest minds, because this would be to reach the roots of the fearful mortality among them. Tenement house laws and health ordinances have their place and should be enforced, but these only reach the border land, as it were, of the difficulty. Within the apartments where the family life goes on is where the laws of health are really broken. It is here, I conceive, that a health officer finds his most important function. It is his by repeated visitation, by wise suggestion, by personal influence, by creating the conviction that he is a friend, so his coming will be welcomed and his advice heeded—by all these and many other means at command—to reach, impress and control the minds of the ignorant masses. Parents can be taught how to sterilize milk, why and how litmus paper should be used as a test for acidity of milk, the value of cereal foods, how they should be cooked and how made palatable, the evils of an excessive use of sweet crackers, animal crackers especially; how the frequent use of head to foot ablutions (as Dr. Edwin Chadwick calls these baths) aid in the maintenance of health and the prevention of sickness; how bedrooms and living rooms can be easily ventilated; why garbage and excrement should not remain in and about the house to offend the senses of sight and smell and to poison the atmosphere; why food should not be kept in bedrooms or bathrooms and near water-closets; why diapers and underclothing soiled with urine should not be dried by the fire in the living-room; what is the use of vaccination; how proper preparation and cooking will render certain cheap, coarse and tasteless foods nutritious and palatable.

Some families might ignore or repel these, and other practical suggestions, but many would welcome them. Boards of health can and should see to it that the drinking-water is ample and good, that milk is at least quite pure and not furnished by cows fed on sour garbage or distillery slops, and kept in unhealthful stables; that house garbage is promptly removed; that plumbing is as it should be; that the sewers are properly flushed and disinfected; that contagious diseases are studied and their spread prevented as far as possible by isolation and

notification to the people; that houses are not overcrowded, and that every facility is afforded for the building of model tenements. The hardworking, conscientious health officer has a wonderful opportunity to save life and increase the comfort and usefulness of the people. If the whole of parentage does not consist merely in loving one's child, but in good blood or heredity, proper food, intelligent care and untiring devotion, the more frequently we can use these factors in the management of institutions for children the better, and the smaller will be the mortality. But what do we find in too many institutions? We might say of some of them, as Florence Nightingale did in 1863 of hospitals: "Strange though it seems, it is quite necessary to lay down the principle that the very first requirement in a hospital is that it should do the sick no harm." There is overcrowding—partly because of a desire to outrival in numbers similar institutions, partly because of insufficient means to extend accommodations, and too frequently because of a niggardly economy, which prohibits a proper supply of food, the employment of intelligent and faithful attendants, and the expenditure of sufficient money to provide proper ventilating and bathing facilities. Though many of the inmates of these institutions come from the lower walks of life and may not have had the best of care at their homes, there is no excuse for cutting off a necessary supply of milk—the most valuable food of childhood—because it is agreed that the expense of running the institution must be lessened; neither is it right to have the floors wet or damp a large part of the time, in the attempt to have them clean. On no ground, other than selfishness, can the practice be defended of sending children who are expected to die out of an institution, so that the published death-rate of the institution shall be small. Such action does not prevent death, but often accelerates it. For what, pray, are institutions for children established unless to care for the feeble, sick and dying as well as for those in health, and to give decent burials if necessary? Careless and prolonged bathing of puny infants in cool or damp rooms is responsible for many a death from capillary bronchitis. Hard and uncomfortable beds, often teeming with vermin, a scarcity of towels and handkerchiefs, the placing of children with gastro-enteric affections, it may be, in the same room with babes having purulent ophthalmia, the insistence upon one woman wet-nursing two infants or having charge of fifteen or twenty little children, a job sufficient to tax the energies of three or four women, the persistent and often underhand opposition to the directions of qualified and fair-minded medical attendants, whose sole aim is to diminish by every means possible a high rate of infant mortality—all of these things are hindrances to the maintenance of health. The bane of too many institutions is too many trustees, and there is a clashing of directions.

The late Professor Dunster, in his report of 1870, showed that owing to no overcrowding, fewer epidemics and better hygienic conditions, infant mortality at the Infants' Hospital, Randall's Island, had fallen in 1868, '69 and '70 from 55.06 per cent. to 46.83 per cent., and then to 36.41 per cent. He believes that unpaid labor is very expensive and deprecates pauper labor in such an insti-

tution, for it does not furnish the "unremitting, judicious and proper care that is needed." In this connection it is well to state the conclusions of the late Dr. Elisha Harris (Letter to Investigating Committee of the Board of Supervisors of King's County, etc., 1874): "The private institutions can save 85 per cent. of mothers' infants and 65 per cent. of hired wet-nurse infants as those institutions are now managed, and it is possible to do much better. . . . The mortality in children past 1½ years of age ought not to exceed 5 per cent. in those under 5 years of age and 3 per cent. of those between 5 and 10 years of age. . . . If in any alias nursery the rate of mortality exceeds 22 per cent. of the infants under 1 year, 10 per cent. in the infants between 1 and 2 years of age, and 6 per cent. in those from 2 to 5 years, and over 3 per cent between 5 and 10 years of age, there is some culpable fault somewhere, and such faults are of the kind that make puny children and insure an increase of pauperism and public burdens."

We may conclude from what is known of institutions for children:

1. That a large proportion of the deaths in them are preventable.
2. That the younger the children, and the larger the number, the greater the mortality.
3. That the mortality can be lessened, but the decrease costs money, time, patience and energy, and to obtain the best results the attending and resident physicians should be reliable, should be given control of all medical and sanitary matters, and should be held responsible for the same.

## PRACTICAL NOTES.

### RECURRENCE OF CANCER OF THE BREAST AFTER AMPUTATION.

From microscopic examinations of carcinomatous mammae amputated by Professor Küster, according to the *Lancet*, Dr. HEIDENHAIN predicted a return of the cancer in twelve cases, because parts of the morbid growth had remained in the wound. In the other cases he diagnosed a radical cure, which diagnosis had proved correct up to the date of the publication of his paper, because the operation had removed the whole of the morbid growth. The usual cause of the recurrence is that only microscopic parts of the gland or the tumor remain on the surface of the pectoralis major. In thin women the whole mammae is firmly attached to the muscle, but in obese subjects small glandular lobules are generally attached to the fascia between the mammae and the muscle, so that in amputation above the muscle small particles of the gland may easily be left. Every mammae in which a single cancer node is found, according to Heidenhain, is largely perhaps *in toto*, diseased. He found the epithelial cells of the acini proliferating in all parts of the mamma, and observed hypertrophy of the per-

iacinous connective tissue, and he believes that these acini remaining in the wound form the origin of the late secondary growths. In the retro-mammary fat there are, side by side with the blood-vessels, lymphatics leading from the mamma to the subjacent fascia, and the latter were, in two-thirds of the cases, full of metastatic cancerous masses. The pectoralis major itself is only affected when a metastatic cancer-node invades the muscle from the fascia, or the original tumor attacks it by its own simple growth. Heidenhain concludes that to make amputation of the mamma more successful it is necessary, even in freely movable carcinomata, not only to remove the whole mamma, but also a superficial layer from the whole of the pectoralis major, and, in tumors which are closely connected with the muscle, to entirely extirpate the latter.—*Boston Med. and Surg. Journal*.

#### TOBACCO IN FRANCE AND GERMANY.

A congress was recently held in Paris to protest against the abuse of tobacco. Explaining why the German who smokes more than the Frenchman poisons himself less, M. Ortolan said that the percentage of nicotine in tobacco is less when the stalks grow closely together and when the leaves are numerous and placed low on the stalk. Hence, in Germany where tobacco growing is unrestricted, the amount of nicotine is less than in the French tobacco, where the industry is regulated by government and the number of leaves to the stalk is limited. French tobacco contains as much as six per cent. of nicotine.—*The Pharmaceutical Era*.

#### FOR YELLOW FEVER.

DR. STERNBERG strongly recommends an alkaline treatment. He tried a formula containing 150 grains of bicarbonate of soda and  $\frac{3}{16}$  of a grain of corrosive sublimate in a quart of water in twelve cases, and all recovered; while of eight cases otherwise treated in the same Cuban hospital, five died. He gives a small wineglass (1 $\frac{3}{4}$  oz.) of this mixture, ice cold, every hour.

#### PERSISTENT VOMITING.

Persistent vomiting, especially that of pregnancy, is often most difficult to overcome and baffles every effort of the physician; indeed, several fatal cases have been lately reported. Dr. Blumensandt, in *L'Union Médical*, says that he has found the following formula invaluable in such cases:

R Hydrochlorate of cocaine . . . . . 3 grs.  
Tincture of anise . . . . . f5ijss.  
Spirits of menthol . . . . . f5ijss.  
Linden-flower water . . . . . f3v.  
Syrup of cinnamon . . . . . f5j.  
M

A dessertspoonful to be given every hour until the vomiting has ceased.—*Med. News*.

#### CINCHONISM AND MEANS OF PREVENTING IT.

DR. COGLITORE, in the *London Medical Recorder* of August 20th, after enumerating the principal symptoms of poisoning by quinine, says that in cases of toxæmia no good is obtained from various other remedies employed as substitutes for quinine (arsenic, salicin, eucalyptus, etc.). He finds that quinine is always well borne if given with ergotin and opium. This is his formula:

R Sulphate of quinine . . . . . grs. xij.  
Bonjean's ergotin . . . . . grs. v.  
Opium . . . . . gr. j.  
M

Make into three powders, and give at intervals of one hour.

Given in this manner, quinine succeeds in the gravest cases and gives rise to no symptoms of cinchonism.—*The Medical Age*.

#### ANTIPYRIN IN CONGESTIVE MALARIAL FEVER.

It is alleged that antipyrin is about to prove an invaluable adjunct to quinine in the treatment of the severest types of malarial fever. From a trial made in a very malarious district of Greece this new use of the drug bids fair to become one of its most beneficial. The significant point in regard to its interaction with quinine seems to be that the antipyrin can be given in the pyrexia, or at any stage when the case is seen. Valuable time may in this way be saved while waiting to introduce the other drug in the advance of the next ensuing pyrexial onset.

#### MENTHOL IN PRURITIC AFFECTIONS.

Menthol is highly recommended by SAALFELD, Berlin, in cases of pruritics of various kinds. He prescribes it either as a wash or as a salve, the formula being:

1. Menthol . . . . . 22-37 gr.  
Spirit vin. rect. . . . . 5j $\frac{1}{2}$ .  
2. Menthol . . . . . 37 grs.  
Ol. Olivarium . . . . . (5ij-5iij.)  
Lanolin . . . . . 5j $\frac{1}{2}$ .

Both preparations have done him excellent service in urticaria, pruritus cutaneus and pruritus senilis.

#### PRESCRIPTIONS FOR THE ADMINISTRATION OF CHLORALAMID.

In the *Therapeutische Monatshefte* for October, DR. A. LANGGARD gives the following formula:

R Chloralamid. . . . . gr. xl.  
Acid. mur. dil. . . . . M v.  
Syrup. simplex . . . . . f5ijss.  
Aq. dest. . . . . f5ij.  
M

This may be taken at one dose.

Used as an enema:

R Chloralamid. . . . . gr. xl.  
Acid mur. dil. . . . . M ij.  
Alcohol . . . . . M xv.  
Aq. dest. . . . . f5ijss. M.

—*Med. News*, November 30, 1889.

## SOCIETY PROCEEDINGS.

## Medical Society of the District of Columbia.

*Stated Meeting, April 3, 1889.*

THE PRESIDENT, CHARLES E. HAGNER, M.D.,  
IN THE CHAIR.

DR. C. H. A. KLEINSCHMIDT presented *Specimen of a Complete Ovary at the Sixth Month of Gestation.*

DR. A. F. A. KING reported the case of

A CHILD EIGHT MONTHS OLD SWALLOWING A  
SAFETY-PIN.

On the morning of July 24, 1888, an infant boy, 8½ months of age, swallowed an ordinary metal safety-pin, measuring when closed one and one-sixteenth inches between its rounded ends; when open, the point diverges from the body of the pin five-eighths of an inch. It was opened when swallowed. On the morning of July 28, the rounded end of the pin, opposite the point, began to protrude from the anus, and was extracted by the fingers of the mother.

The mother relates that at the time of the accident she had just removed the pin from the child's clothing and stuck it carelessly in her dress over the neighborhood of her breasts, from whence it fell into the infant's mouth. She stated that the child acted as if he wanted to throw up and "choked as she had never seen him choke before." She passed her finger into the mouth, but could not touch the pin. In the absence of medical advice, a teaspoonful of castor oil was administered and retained. The child had for some months been "bottle fed," and was also allowed to eat bread and milk. A physician (whose name I do not know) ordered the same diet to be continued, adding thereto slipperyelm water as a drink, and directions to keep the child quiet.

The child suffered but little uneasiness until the third day when fretfulness and indications of pain, gradually increased, and got still worse during the night preceeding the fourth morning, when, while having an action from the bowel, the mother discovered the pin and removed it from the anus as previously stated. The infant at once became easy; had a prolonged sleep; and no ill effects have since resulted from the accident.

The case, I think, is of interest, chiefly from the remarkable good luck which determined the pin to keep going right end foremost in its circuitous route through the alimentary canal. As long as the projecting point continued to look backwards, it could pass quite as easily as a copper cent., which latter measures three-fourths of an inch in diameter, and is therefore one-eighth of

an inch wider than the diverging extremities of this open safety-pin.

It is quite probable that the passage of the pin, after it had reached the stomach, was painless, and that the pain and fretfulness during the third and fourth days were produced by the foreign body, impinging upon the sensitive sphincter ani.

If the anus had been explored during the third day, possibly the pin could have been extracted twenty-four hours sooner than it was, and much suffering by the infant and worry of the mother prevented.

I ought, perhaps, to state that I have never seen this child. I had treated the mother, before her marriage, for stenosis of the cervix, and the happy result of Goodell's method of rapid dilatation, after some years of menstrual pain, so impressed the patient, that her first thought, when the child swallowed the pin, was to send to me for advice. I ventured to predict that the pin would probably pass without injury, and told her to do nothing, but assist the exit of the foreign body if it should lodge within the anus. Some weeks later, she wrote me that the pin passed all right, and afterwards at my request, sent me the more prolonged account from which I have gleaned the facts presented in this paper, and which, from my knowledge of the lady, I feel quite sure may be relied upon.

DR. SMITH thought the report of the case introduced a very interesting subject for discussion. Some years ago a child had been brought to his house because it had swallowed a penny; he advised the parents to let it alone; and in a few days the coin was passed from the rectum. A few days ago a doctor brought his own child to Dr. Smith's office, and stated that it had swallowed a metal whistle about an inch in its largest diameter. He advised the father to allow it to pass without administering cathartics, and the foreign body was passed from the rectum the next morning without any discomfort to the patient. He was surprised at this because the diameter of the whistle was so much greater than that of the anus. Some years ago he had been called to see an infant, and learned from the mother, who was greatly distressed, that it had swallowed an ordinary rubber nipple. He did not believe the history, and Dr. W. G. Palmer, who came in while he was there, coincided with this belief. They advised the mother to let the infant alone, and went home. Shortly after they received a message that the nipple had been found on the floor. The important question to determine is whether the child has swallowed a foreign body. In many instances the parents become alarmed because they cannot find articles, and immediately conclude they have been swallowed.

THE PRESIDENT reported a case similar to that reported by Dr. Smith, where a colored child

about 7 years old, had swallowed a whistle. Dr. Gilbert brought the child to his office, and it located the pain about the lower end of the œsophagus. Dr. Hagner passed a probang and felt the foreign body and pushed it into the stomach. As it passed through the cardiac orifice there was a distinct whistle. Some days after it was passed from the rectum without any inconvenience.

DR. THOMPSON had recently seen a boy who had swallowed a whistle. There was no suffering; but he rejected food soon after taking it; and there was a peculiar noise on sleeping. He gave him some water, but it was regurgitated in a few seconds, which led him to believe the foreign body had lodged in the œsophagus. He tried to pass the probang, but the child was so obstreperous that this failed. He told the parents to bring it back again, but as he had not heard from them it was probable that some other doctor had been consulted. Pennies are frequently swallowed. He had removed three from the rectum of a child in the Children's Hospital; they had been there for sometime. It is very singular that so little serious effects result from swallowing foreign bodies.

DR. SOTHORON said that his son had swallowed a whistle, but had not suffered from it although it was about the size of a nickel. He gave him a dose of castor oil and the whistle was passed in about four days. About a year ago he had removed a pin from the rectum of a child; it was located two and a half or three inches from the anus and was at first supposed to be bone.

THE PRESIDENT thought it would be well to consider the removal of foreign bodies lodged in the œsophagus and trachea. If the body is lodged in the œsophagus should it be drawn up, pushed into the stomach, or should cathartics be given? If the feces are solid the body may become surrounded and pass through the alimentary canal without doing any harm; but if the feces are liquefied by cathartics the fluid will pass the foreign body and allow it to lodge in the tract. Consequently he favored the use of constipating food until the body was passed. Sometime ago Dr. Peter brought a patient to him because a foreign body had lodged in the œsophagus. He introduced an umbrella-shaped probang, and removed a large piece of meat through the middle of which was a large pin. How the pin got there no one knew.

DR. CALDWELL: The President in speaking of the inadvisability of cathartics in patients who had swallowed foreign bodies would probably explain a case seen by him sometime ago. The mother stated that the child had swallowed a brass button, and had administered emetics before she sent for him, but the body was not ejected. He did not think the child had swallowed it, but nevertheless ordered several doses of castor oil

without any perceptible effect. In about two weeks the button was passed from the rectum. He now thought the fecal matter was probably liquefied and passed by the foreign body without disturbing it.

DR. J. FORD THOMPSON: Dr. McArdle had seen a case of typhlitic abscess with him sometime ago in a young woman several months' pregnant. He had declined to operate because the woman was dying. At the post-mortem a large black pin with a broad head was found in the appendix, the point having punctured the abscess wall. He had operated to-day for the same condition in a young lady about 20, who had swallowed a piece of a writing pen about seven years ago. He explored the abscess, but could not find any foreign body. Artificial teeth are sometimes swallowed and become impacted in the œsophagus, when it is quite impossible to dislodge them except by œsophagotomy. Usually foreign bodies pass to the lower part of the œsophagus when œsophagotomy is impossible. In such cases gastrotomy would be indicated and is occasionally performed. Many times very large foreign bodies pass through the alimentary tract without doing any harm; on the other hand very small ones, as seeds, pills, etc., will cause obstruction or fatal inflammation.

DR. SAMUEL C. BUSEY reported:

A CASE OF EXOPHTHALMIC GOITRE TREATED  
SUCCESSFULLY WITH SULPHURIC  
ACID AND STROPHANTHUS.

In the *Medical News* of Nov. 3, 1888, Dr. W. E. Magruder, of Olney, Md., reports the "successful treatment of a case of exophthalmic goitre by sulphuric acid." The case presented the usual symptoms of the disease, "enlargement of the thyroid gland, with decided pulsation, protrusion of the eyeballs, palpitation of the heart, frequent pulse, anemia, etc." After trial of various remedies usually given in such cases, he prescribed the aromatic sulphuric acid in combination with digitalis and ergot, from which the patient derived much benefit, but in consequence of its disagreement with the stomach, the ergot and digitalis were discontinued, and 20 drops of the aromatic sulphuric acid was given every four hours. Her improvement was more rapid, and finally, a complete cure was effected. Dr. M. attributed the successful result of the treatment to the tonic influence of the acid upon the vasomotor nerves.

In THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION of the same date appeared a contribution by Dr. D. R. Brower, of Chicago, entitled "Exophthalmic Goitre, and its treatment by Tincture of Strophanthus," in which he reports several cases treated with this drug, resulting in cure. In one case the patient had been under the ordinary treatment for three months "without any

abatement of the symptoms." In the second case the patient, a female, aged 52, had suffered with the disease for eighteen months. He refers also to a case treated by Dr. Bridge with strophanthus and tonics, with rapid recovery, and to a case in which Dr. Ingals had employed the same remedy with marked benefit.

During the week succeeding the appearance of these reports I was called to see a young lady suffering with the disease. In her case the cardiac and thyroid symptoms were well marked. The exophthalmos was perceptible, but not prominent. It was more marked in the absence of harmony in the movements of the eyeballs and upper lids than in protrusion of the eyeballs. The right side of the thyroid gland was much larger than the left, but the enlargement at the base of the neck compelled her to enlarge her collars and to loosen the neck bands of her clothing. Her pulse was frequent and excitable, complained of palpitation and difficult respiration, especially when ascending steps. Slept badly, sometimes lying awake all night, was nervous, irritable, anæmic, without appetite, constipated, and had a slight cough. In general appearance she looked like one suffering with phthisis pulmonalis. I ordered two drops of the tincture of strophanthus every six hours, and ten drops of aromatic sulphuric acid every four hours, an easily digested and nutritious diet, food to be taken during waking time every four hours, early retirement and remaining indoors during inclement weather and after sunset. The course of treatment was twice interrupted, once by the illness and death of a member of the family, and again by a severe attack of bronchitis, induced by indiscreet exposure in making a visit to the cemetery. Improvement was manifest soon after the beginning of the treatment, and now she seems to be perfectly well, with entire disappearance of the thyroid enlargement. The action of the heart is good, her appetite is excellent, bowels regular, sleeps well, is bright and cheerful. She is vigorous, with rosy cheeks, and a gain of twenty-five pounds in weight.

Whilst the result has been as satisfactory, the progressive improvement in this case was not as rapid as in either of the cases reported by Drs. M. and B., probably because the drugs were not given in as large and increasing doses. The plan of treatment established at the beginning was persistently pursued to the end, with the exception of the interruptions referred to.

DR. W. W. JOHNSTON, in opening the discussion, said: There was probably no disease in which the treatment sometimes accomplished so little good as exophthalmic goitre. The cases may be divided into two classes, viz., first, the subacute, which are the most curable and yield promptly to vigorous treatment, the principal element of which is rest; second, the chronic, which

may be subdivided into two varieties, those which are curable and those which are not. As the successful remedies used are often empirical ones, and those given in obedience to a theory frequently fail. He believed exophthalmic goitre to be a disease of the central nervous system, leading to congestion of the thyroid gland, of the fundus of the eye, and to cardiac disturbances. It is analogous to physiological and other pathological congestions.

The regulating vaso-motor centers are disturbed, leading to local congestion. It is not known why this congestion should take place in the orbit and thyroid, but it follows the disturbance of certain nerves. The lesion is undoubtedly in the medulla oblongata, and acts upon the pneumogastric and vaso-motor nerves. The only effectual remedy to accomplish any good should go to the seat of the disease. As we have no such agent we resort to those which act by relieving the distressing symptoms and local congestions. Hence the use of ergot, which acts upon the pathologically dilated peripheral vessels. Ergot is said to have proved valuable and favorable in the cases reported. Then there are those remedies which act upon the heart by regulating its disturbed action. There must be two distinct pathological conditions, as the thyroid and cardiac symptoms are not always associated, and ergot and heart-calming remedies are both called for. The action of the heart is the most serious symptom, as it disturbs the blood supply to the various organs and enfeebles digestion. In the experiments with strophanthus it has been shown that it slows and then enfeebles the heart's action if it is pushed to its full physiological effect. This slowing of the heart is important, and we may expect more from strophanthus than digitalis.

He had seen quite a number of cases. In one, an acute case, the patient was put to bed and kept quiet; digitalis and ergot were administered and recovery took place in three weeks. In another, a lady, the heart's action was feeble and the exophthalmia marked. Absolute rest was enjoined and ergot and digitalis administered. She recovered and is now well. In another, a female school teacher, all the symptoms were well marked. She was afterwards under the care of Dr. Weir Mitchell who treated her principally by rest and galvanism. She afterwards went to Atlantic City and gained very much in a short time. Rest is the most important part of the treatment, and no method will prove effectual without absolute rest of mind and body. Some patients are irritable, others hysterical, and a few have delusions. In these cases there is some congestion of the brain. Electricity has been warmly advocated by some but had not proved beneficial in his cases, either as a local application or general tonic. He hoped we had found in strophanthus a new and valuable remedy, and thought

it should be pushed until some decided effect was seen, as in small doses it seemed to be of little value.

DR. MURRAY asked Dr. Johnston the duration of treatment in his favorable cases.

DR. JOHNSTON: The cases were subacute and were cured in about six weeks. In some the treatment had extended over several months, but was not persistent. Improvement was steady after rest was secured. Many chronic cases do not get into our hands until numbers of physicians have treated them, so it was impossible to fix the time of their duration under any plan of treatment.

DR. MURRAY had asked the question so that he could compare results and form an idea of the value of the new treatment.

DR. TONER had seen a case of thirty years standing. At first he was hopeful that treatment would prove beneficial, but within two years her condition was unchanged, in spite of continued good health. This was a sister in one of the asylums of the city, and who now lives in South Bend, Ind. One case had recovered in six months. There was considerable heart disturbance, for which he gave digitalis. The man lived in Cumberland, Md., and he had only seen him four times. He was tall, spare and active, with light hair and eyes; and the disease occurred suddenly. Six years after he died of heart disease.

THE PRESIDENT: Would mental worry and anxiety act as exciting causes in production of exophthalmic goitre?

DR. JOHNSTON: Valvular disease of the heart is not present in the beginning of the disease, but is finally produced in those chronic cases in which the heart is subjected to continual strain. In a case reported by Trousseau cirrhosis of the thyroid gland and liver were found; these changes being the ultimate result of long-standing congestion.

DR. MURRAY: It was only a question of time when the heart would become involved. Heart disease usually destroyed life.

DR. BUSEY: In answer to Dr. Bermann's question as to the cause of the disease in his case, said he could not give the cause. She was anæmic, and had been in feeble health for several years. The goitre, however, was not long in developing. As to the noises in the ears, he was aware that they had been mentioned by more than one author; but they were not complained of by his patient. Exophthalmic goitre may exist with or without exophthalmia or heart disease, or one of these phenomena only may exist. The cases differ in degree and symptomatology.

In reply to Dr. Bermann's question he said he did not believe that either strophanthus or digitalis had a cumulative effect; he had been taught that digitalis possessed such quality, but he had

never seen it. The dose of strophanthus is susceptible of being increased until six or eight drops are taken every four hours. He had never given strophanthus in large doses. He believed that it was more variable in strength than digitalis.

Various theories as to the cause of exophthalmic goitre have been advanced, but none of them explain it. The theory of its nervous origin came nearer the truth. Sulphuric acid is not unlike ergot in its action. Hanfield Jones considers it a most valuable tonic to the vaso-motor system.

## FOREIGN CORRESPONDENCE.

### LETTER FROM LONDON.

(FROM OUR OWN CORRESPONDENT.)

*The Notification of Infectious Diseases Act—Dr. Jules Simon and the Treatment of Diphtheria—The Pasteur Institute Fund—Hydrochlorate of Pilocarpine in Hystero-Epileptic Attacks—Report of the Royal Commission on Vaccination—Miscellaneous Items.*

The Notification of Infectious Diseases Act has now come into operation, compulsorily as regards the metropolis and permissively as regards provincial authorities. Under the provisions of the Act notification must be given, in the case of certain infectious maladies occurring, both by the head of the household (or in his default by various other persons who are enumerated, including finally the occupier of the building), and also by the medical practitioner attending the patient. As the doctor is under a legal compulsion to do his duty in this respect he need not fear that he will give offense to a foolish employer by disclosing family secrets, and moreover, his diligence will be sharpened by the receipt of a small fee from the local authority to whom he makes the formal notification.

Dr. Jules Simon, who has written much on the treatment of diphtheria in young children, has recently visited this country. It appears he is opposed to the use in this disease of mercurials, of chlorate of potash, of borax, of opium and of emetics. The treatment which he advocates is chiefly local and consists of energetic swabbing made every hour with the following solution:

R. Salicylic acid, . . . . .	0.5 to 01 grams.
Alcohol q. s. to dissolve. .	
Glycerine . . . . .	40 "
Infusion of eucalyptus . .	40 "

The same practitioner also prescribes touching the pseudo-membrane, when very thick and adherent, with a mixture of equal parts of glycerine and perchloride of iron, this application to be made two or three times a day. He also recommends sprays of eucalyptus and of thymol. For nasal diphtheria the application of a mild sulphur

ointment, 1 part to 7, is likewise recommended. To combat the glandular enlargement and engorgement he has the following, well rubbed in:

R. Ext. of belladonna . . . . .	2 parts.
Iodide of potassium . . . . .	1 "
Lard . . . . .	30 "

The patient's room should be kept at a temperature of 59° F., its atmosphere should be constantly renewed, though it is better that the air from outside should enter through another room, not directly from the open air. The patient Dr. Simon keeps in an aromatic and slightly moist atmosphere, obtained by heating alternately, over a spirit lamp, shallow tin dishes containing tar, and others containing eucalyptus leaves and water. Copaiba and cubebs seem, he says, to have some specific virtue in this disease and are sometimes prescribed by him as adjuvants. If the larynx is invaded by pseudo-membrane, emetics are prescribed early, and tracheotomy performed as soon as ever the symptoms of asphyxia show themselves.

A meeting of the Committee of the Pasteur Institute Fund has been held at the Mansion House. The Lord Mayor presided and there were present Sir Henry Roscoe, Professor Fleming, Professor Michael Foster, F.R.S., Mr. Ernest Hart, Professor Ray Lankester and Dr. Armand Ruffer. It was unanimously resolved on the motion of Professor Ray Lankester, seconded by Mr. Ernest Hart, "that the Lord Mayor be requested to transmit to M. Pasteur for the use of the Pasteur Institute the sum of 40,000 f., in grateful recognition of the services rendered by him in the successful treatment of more than 200 British subjects bitten by rabid animals, and that the Lord Mayor be desired at the same time to express to M. Pasteur the high appreciation of the subscribers of the great benefits which he has conferred on science and humanity."

Dr. Samuel B. Lyon reports the case of a married woman æt. 30, in whom the convulsive seizures had the characteristics of hystero-epileptic attacks and who was relieved by a hypodermic injection of 18 gr. of hydrochlorate of pilocarpine given over the left ovary. Her temperature, which had been 103.4°, fell to 101.2°. The convulsive movement ceased, consciousness gradually returned and a quiet sleep followed. In this case inhalations of amyl nitrite and ether had only temporarily quieted the spasmodic condition.

The first report of the Royal Commission on Vaccination has just been issued. It contains little else than the minutes of the evidence of four witnesses, Sir John Simon, Dr. W. Ogle, Mr. R. Thorne-Thorne and Dr. Rauch. The Commission began by drawing up a plan of operations which involved the separation of the evidence under six heads. They proposed to begin with the historical and statistical case in favor of vaccination. This will be followed by the arrange-

ment under and administration of the present law, after which inquiry will be made into the case against vaccination and, if continuing to be made compulsory, the reply to those objections and the suggestions of substitutes for the purpose of preventing smallpox. Finally evidence will be taken of suggestions for the improvement of the present law or its administration, with the object of removing objections to vaccination or making it more effective. This programme, when it has been carried out, ought to be conclusive enough to set the disputed points at rest. The report now issued is but a little part of the whole, for the Commissioners say the evidence coming within the first item of their list is not yet ended. So far as it goes, however, there is in that evidence an enormously strong case for vaccination.

At the Pathological Society of London a specimen of non-alcoholic cirrhosis of the liver was shown. The specimen had been taken from the body of a clergyman aged 63, who had been a total abstainer for thirty-seven years. During the last five years of his life he had suffered from repeated attacks of hepatic colic, which lasted for periods of from seven to ten days, and during these attacks he used to pass gall stones and become jaundiced. In the last two years of life the patient had symptoms of angina pectoris, and six weeks before death ascites appeared. At the post-mortem examination the large arteries were found to be hard and atheromatous, particularly the coronary arteries. The liver, upon inspection, presented the ordinary characteristic of cirrhosis, being hobnailed, hard and pale. The gall-bladder was contracted and bound down to the liver substance by dense adhesions. It contained one large stone and several smaller ones. The liver was infiltrated by a very vascular small-celled growth, which had destroyed the lobules by pressure; the connective tissue was entirely interlobular, the liver cells had not undergone any fatty change, nor was there any abnormal development of pigment. It was generally considered that the irritation of the successive gall-stones and obstruction would be sufficient to account for the development of the fibrous tissue.

An anonymous writer has drawn attention to the value of cocaine as a hæmostatic, and states that for three years past he has given subcutaneous injections of hydrochloride of cocaine to produce local anæsthesia, and noticed that little or no bleeding was occasioned. This led him to use charpie imbibed with a solution of cocaine, namely, hydrochloride of cocaine 1 gram, alcohol 5 drops, cherry laural water 5 grams.

Hyoscine, which is taking the place to some extent of hyoscyamine, when injected at the dose of  $\frac{1}{65}$  grain subcutaneously, produces calm and induces sleep in maniacs and sufferers from alcoholic delirium.

Sir Joseph Lister and Dr. Priestly will represent the Edinburgh Medico-Chirurgical Society on the committee of the International Congress of Hygiene and Statistics, London, 1891.

Dr. Lauder Brunton, F.R.S., has arrived at Hyderabad to take part in the chloroform investigation.

G. O. M.

## NECROLOGY.

### Dr. J. K. Bartlett.

Dr. J. K. Bartlett, of Milwaukee, Wis., died at Berkley, Cal., on the 26th of November, 1889, in his 73d year. Born in Portsmouth, N. H., 1816, he entered Yale College in 1834, and graduated from the Medical Department in 1841. In the same year he commenced the practice of his profession among the pioneers of Milwaukee, and remained in active practice for forty-five years. Latterly being the subject of bronchial catarrh and cancer of the lip, in the fall of 1887, he went to California in the hope that a milder climate would benefit his failing health. Some benefit he did derive, but the cancerous affection of the lip made very rapid progress, extending to the tongue and throat the power of speech was lost and death resulted from starvation. The following extract from one of his notes to his attending physician, shows how gladly he counted relief in death: "Weakness is increasing daily, the onward progress towards the dark river appears to hasten, and yet the briik is not in sight. It is well so, for I have some matters to attend to before the plunge." A firm believer in, and a strong advocate of cremation, he directed in his will that his body should be cremated. This was done at Los Angeles, Cal., and the ashes sent to Milwaukee for interment in the family burying ground.

To many members of the American Medical Association, he was well and favorably known. For over a quarter of a century he regularly attended the annual meetings, and took an active part in the proceedings. He served as a member of the Executive Council from the time of its creation until declining health caused him to resign; was vice-president in 1872, and chairman of the Section of Obstetrics, at the Cleveland meeting in 1883, when he delivered an able and scholarly address on the "Progress in Obstetrics and Gynecology." His views as to a higher standard of medical education were very advanced; he was a strong supporter of the Code of Ethics, the teachings of which, in his professional life, he carried out both in the spirit and to the letter. To the last he maintained a keen interest in the Association and the profession, was familiar with all the recent literature, not only in English, but also in French and German, with

both of which he was familiar. In his own State he was equally active in society work, having been instrumental in organizing, at various times, not less than six different societies, all of which are now obsolete with the exception of the Wisconsin State Medical Society. Of this he was an ex-president, for many years a member of the board of censors, and at the time of his decease an honorary member. On leaving Milwaukee, he presented his medical library to a medical club in that city, which now bears his name.

As a practitioner, he was eminently successful—enjoying the confidence of both fellow-practitioners and patients alike. By the former he was eagerly sought after in consultation, and by the latter regarded as their trusted and esteemed friend. Aside from his professional attainments, his acquaintance with general literature was very extensive, as his miscellaneous library gave evidence of. He was one of the corporate members of the Young Men's Association, now merged in the Public Library, was elected president in 1853, and for many years very active in its behalf, as a member of the board of directors.

The very choicest books which belonged to the Association, were many of them of his personal selection, to which work he gave no small amount of his time and labor from 1851 to 1861. He was fond of music, and had no inconsiderable cultivation in the art, and during an early period of his career he was active in musical circles.

## BOOK REVIEWS.

### THE MEDICAL NEWS VISITING LIST FOR 1889.

This valuable little work has been thoroughly revised, and brought up to date in every respect. Three styles are published as heretofore. The weekly edition is arranged for thirty patients, the monthly edition for 120 patients, is undated and good for any year. The third, or perpetual edition is also undated, and is good for any year.

The method of arrangement is the best that medical men have been able to devise. In short, every need of the physician seems to be anticipated in this last revision of *The Medical News Visiting List*. Each style is in one volume, bound in handsome red leather, with pocket and pencil. Price \$1.25.

### THE STORY OF THE BACTERIA AND THEIR RELATIONS TO HEALTH AND DISEASE. By T. MITCHELL PRUDDEN, M.D. 16mo, cloth; pp. 143. New York and London: G. P. Putnam's Sons. 1889.

As may readily be conjectured from the title, this is a book which approaches the border line between science and general literature; indeed, it

really steps over a little way into the territory of the latter, where it will doubtless have a good reception, such as it deserves. One can scarcely imagine a technical, scientific subject treated in a more delightfully interesting manner than this one has been. Dr. Prudden certainly has the faculty of making science racy for non-scientific readers. Although this little book is evidently designed for popular reading, it will be found to be replete with interest for the average medical reader as well.

**AN EXPERIMENTAL STUDY IN THE DOMAIN OF HYPNOTISM.** By DR. R. VON KRAFFT-EBING, Prof. Psychiatry, University of Graz. Translated from the German by CHAS. G. CRADDOCK, M.D., Assist. Phys. Northern Michigan Asylum. Pp. viii, 129. New York and London: G. P. Putnam's Sons. 1889.

By those who are interested in the subject of hypnotism, a subject, indeed, whose claims to practical importance are being more and more pressed upon the medical profession, this contribution will doubtless be read with attention. It is occupied entirely with an account of a large number of extraordinary experiments performed upon a young Hungarian woman who was unusually susceptible to psychological influences. To the author's mind they afford abundant proof of the correctness of the view that hypnotism does not depend upon so-called animal magnetism, but upon a psychical (moral) influence exercised by the experimenter over the subject. The author congratulates the profession that so important a subject as hypnotism has been taken from the hands of charlatans to be developed by scientific inquiry until it has come to occupy a conspicuous place in the domain of science.

**ORIGINAL INVESTIGATIONS OF CATTLE DISEASES IN NEBRASKA—1886-1888.** By FRANK S. BILLINGS, while Director of the Patho-Biological Laboratory of the State University of Nebraska. Pp. 280. Lincoln, Neb.: State Journal Co., Printers. 1889.

This volume contains articles on "The Southern Cattle Plague and Yellow Fever," in which the author describes some points of resemblance between the two diseases; an article on "The Corn Stalk Disease;" an article on "The So-called Hydrophobia in Cattle;" an article on "Contagious Inflammation of the Cornea in Cattle;" and an article on "A Singular Disease of the Sexual Organs in Cows."

Dr. Billings' labors are too well known and appreciated both at home and abroad to make any extended description of the character of his work necessary. It is sufficient to say that an immense amount of original investigation is embodied in his publications, all of which bear the stamp of

the enthusiastic observer. The present volume contains a number of excellent colored plates illustrative of pathological and bacteriological features of the diseases considered.

In a final note Dr. Billings alludes to the closing of his work in connection with the State University of Nebraska. It is understood that he has taken up his permanent residence in Chicago, where it is hoped that he will find abundant means of continuing investigations which have proved so valuable to the stock-raising interests of this country.

## MISCELLANY.

**THE PARIS AWARD.**—Among the thousands of exhibitors who have made a display of their wares at the Paris Exposition this year, less than one-half received any award; the remainder received honorable mention, bronze, silver and gold medals, but to a very limited number was the Grand Prize awarded. The Grand Prize was awarded to Nestlé's Milk Food. This is the second occasion on which this great distinction has been conferred on Nestlé's Milk Food.

## LETTERS RECEIVED.

Dr. G. H. Simmons, Lincoln, Neb.; E. B. Treat, New York; Dr. W. H. Delong, Pikesville, Pa.; J. H. Bates, New York; Dr. Will. Jennings, Richmond, Ky.; Dr. F. R. Van Kirk, McKeesport, Pa.; Dr. H. F. M. Nary, Princeton, Ky.; D. B. Lefever, Ephrata, Pa.; Dr. F. H. Long, Madison, Neb.; Dr. D. C. Patterson, Washington, D. C.; Dr. G. A. Brodie, Claremont, Ont., Can.; Dr. R. J. Dunglison, Dr. De F. Willard, Philadelphia; Dr. N. White, Chicago; Dr. Samuel S. Adams, Washington, D. C.; Dr. W. W. Jaggard, Chicago; Thos. Leeming & Co., New York; P. Blakiston & Co., Philadelphia; Dr. W. T. Dougan, Vandalia, Mich.; Dr. P. Hooper, William R. Warner & Co., Philadelphia; Dr. A. F. Walter, Gladbrook, Ia.; Dr. Austin Flint, New York; A. H. Roffe & Co., Boston; Long Island College Hospital, Brooklyn, N. Y.; T. W. Hannaford, London, Eng.; Dr. J. E. Clark, Detroit, Mich.; Triibner & Co., London, Eng.; Dr. L. Turnbull, Philadelphia; Dr. A. Holton, Harker's Corner, Ill.; Dr. Wolfred Nelson, New York; Dr. C. A. Foulke, Argentine, Kan.; Dr. Daniel LaPerte, Detroit, Mich.; Journal of Cutaneous and Genito-Urinary Diseases, New York; Dr. D. ### THE ETIOLOGY OF TYPHOID FEVER.

*Read in the Section of the Practice of Medicine, Materia Medica and Physiology, at the Fortieth Annual Meeting of the American Medical Association, June, 1889.*

BY VICTOR C. VAUGHAN, M.D.,  
OF ANN ARBOR, MICH.

*Mr. Chairman and Gentlemen of the Section:*—As my time is limited I shall waste no words in introductory remarks, but shall endeavor to get at the gist of my subject immediately. In 1880 Prof. C. J. Eberth, of Zurich, in eighteen out of forty cases of typhoid fever, found in sections of the spleen and mesenteric glands a bacillus which is distinguished from the ordinary putrefactive bacilli by the difficulty with which it takes up the aniline stains. At the same time Eberth reported that in twenty-four similar examinations of those dead from other diseases he was unable to detect this bacillus. From these facts the distinguished Swiss investigator thought himself entitled to claim that he had discovered the true germ of typhoid fever. Even before Eberth's report appeared, Koch had seen and photographed the same bacillus, so that this germ is by some called the Eberth bacillus and by others the Koch-Eberth bacillus. For the sake of brevity, and without expressing any opinion as to the priority of discovery, I shall in the subsequent pages refer to this microorganism as Eberth's germ or Eberth's bacillus.

This organism is now generally regarded as the true cause of typhoid fever, and I shall give my attention first to the grounds upon which this belief is founded. Has it been conclusively demonstrated that the Eberth germ is the sole and sufficient cause of typhoid fever? To what extent have the four rules of Koch been complied with in the study of this germ? Are there any reasons, outside of these rules, for founding a belief either for or against the specific nature of this bacillus?

In the first place, is this organism found invariably in typhoid fever? As has been stated, in his first report Eberth found it in eighteen out of forty cases; but since that time methods have been perfected and many other investigators have

studied this point. In the examination of twenty-eight bodies dead from typhoid fever Gaffky found the Eberth germ in twenty-six; Fränkel and Simmonds reported it in twenty-five out of twenty-nine cases; Seitz in twenty-two out of twenty-four; Rietsch in thirty-five out of thirty-six, and Kowalski found it present in each of twenty-nine cases.

Without citing further authorities I may say that the number of cases of genuine typhoid fever in which this germ has not been found, when the examinations have been made by competent men, is so small that we are justified in claiming that the first of Koch's rules has been complied with. Indeed, in reading over the great number of cases referred to in the volumes of Baumgarten's "Jahresbericht," in which the Eberth germ has been reported to be present, one becomes somewhat suspicious of the universality and readiness with which this organism has been detected. Gaffky and others found it always present in the mesenteric glands and spleen, often in the liver, and not so frequently in the kidney. In the intestine it has been found in the early stages in the swollen follicles and plaques and in the deeper layers, before there is any necrosis; but with the advent of ulceration there is found secondary invasion. But in addition to these organs, the Eberth germ has been reported by Chantemesse and Vidal in the lungs of typhoid patients with bronchitis, broncho-pneumonia and pneumonia. The same observers report the germ in the brain, Curschmann in the spinal cord, Zenker and Hoffmann in the voluntary muscles and in the marrow of the bones, and Reher, Neuhauss and Chantemesse and Vidal in the placenta of typhoid patients. In twenty samples of blood taken from the finger, during life, of typhoid patients, Meissel reports the finding of this germ in nineteen. Neuhauss examined the blood taken from the eruptive spots in typhoid fever with success. Maragliano and others examine the blood taken from the spleen during life as a means of diagnosis. The Eberth germ has been found in drinking water by Dreyfuss, Brisac and Vidal, Michael, Noers, Chantemesse, Loir, Thoinot, de Blasi, Galbucci, Beumer, and others. Granting that these observers have not been mistaken in the nature of the germs which they have found,

we must admit that the Eberth germ is widely distributed.

That the second of Koch's rules has been complied with there is no doubt. Pure cultures of this germ are to be found in every bacteriological laboratory. It grows readily in our artificial media, and its characteristics of growth are well known.

The attempts which have been made to induce the disease in the lower animals by inoculation with this germ are numerous and interesting. I shall not attempt to review all of these, but will call your attention to some of the more important ones. The first to experiment with pure cultures was Gaffky. To five Java apes he fed daily cultures without any results. Later these animals died of tuberculosis, and section showed no lesions resembling those of typhoid fever. Equally without result were two other experiments upon apes, in one, the inoculation being made directly into the blood, and in the other, in the tissues over the sternum. Gaffky also inoculated rabbits, Guinea pigs, rats, mice, pigeons, a chicken and a calf—all without result. In these the inoculations were made directly into the blood vessels or into the peritoneal cavity.

The experiments of E. Fränkel and Simmonds seemed at first to prove that the Eberth bacillus is pathogenic to some of the lower animals. These experimenters suspended the germ taken from potato cultures in sterilized water and injected this either directly into the blood or into the peritoneal cavity. Nineteen out of thirty-two rabbits and twenty-seven out of thirty-one mice succumbed to this treatment. These animals survived the injections from a few hours to four days, the majority dying on the first day. The symptoms observed consisted of lessened response to surroundings, lessened inclination to move, loss of appetite and, in many, diarrhoeal discharges. Section showed enlargement of the spleen and mesenteric glands, and swelling of the intestinal follicles. In some there were observed enlargement of the axillary and inguinal glands, ecchymoses of serous membranes, inflammatory redness and hæmorrhage in parts of the intestines and parenchymatous swelling of the liver and kidneys. In no case was there suppuration at the point of inoculation. In the spleen, mesenteric glands, liver, kidneys and Peyer's patches the bacillus could be detected. However, the abundance of the bacilli did not correspond with the extent of the macroscopic changes. From these experiments Fränkel and Simmonds concluded that they had successfully transmitted typhoid fever to these animals.

Independently of the above, Di Vesta inoculated with fatal results rabbits and Guinea-pigs. The lesions were not so marked as those found by the Hamburg investigators. Later, A. Fränkel inoculated Guinea-pigs with the Eberth germ after

the manner employed by Nicati and Rietsch in their experiments with the cholera bacillus, and which consists in introducing the germ directly into the duodenum, either with or without ligation of the bile duct. Of the fourteen animals thus treated seven died. The anatomical changes observed were similar to those found by E. Fränkel and Simmonds.

Seitz, employing Koch's method for producing cholera in Guinea-pigs, found that seven out of sixteen animals died within forty-eight hours, and one other after four days. The germ could be detected in the intestines, but not in other organs. Intravenous and intraperitoneal injections of the germ produced results similar to those obtained by E. Fränkel and Simmonds.

Beumer and Peiper confirm the observations made by E. Fränkel and Simmonds, and A. Fränkel and Seitz, but interpret their results in a wholly different way and reach a diametrically opposite conclusion. In the first place they find that the effect upon the animal is in direct proportion to the amount of the culture injected; an amount which is small, but which still contains many thousand germs, fails to produce any symptoms. Secondly, they prove that the Eberth germ does not multiply in the body of the animal, but, on the contrary, soon dies. Thirdly, they show that the same symptoms and identical structural changes result from injecting like amounts of certain well-known non-pathogenic bacteria, such as bacillus subtilis, the greenish-yellow liquefying bacillus of water, the white bacillus of water, and others. Thus they show that the death of the animals is due to intoxication, and not to infection; also, that the intoxication is not specific, inasmuch as it is produced with equal facility with other bacteria.

Finally Sirotonin demonstrates that the same symptoms and pathological lesions are produced by sterilized and non-sterilized cultures of the Eberth germ. This completes the proof that the effects observed are not due to the growth of the germ within the body.

To sum up the evidence which we have upon this point, we may say: (1) The Eberth germ is found invariably in the bodies of those dead from typhoid fever. (2) It has been isolated and grown in pure cultures. (3) All attempts to induce typhoid fever in the lower animals by inoculation with this germ have so far been without success. (4) Experiments show not only that the germ fails to multiply in the lower animals, but that, when introduced by inoculation, it soon dies.

I think that every bacteriologist will agree with me in the conclusions which I have just stated; but the bacteriologist stops here and says: "The lower animals do not have typhoid fever, and we must not conclude from the failure to induce this disease in them with Eberth's germ

that this bacillus is not the true cause of typhoid fever." "If we could experiment upon man," says he, "I have no doubt that we would be successful." For these reasons I wish to discuss this germ from the standpoint of the chemist. I think that it is now time for us to supplement the rules of Koch with the following, which should be insisted upon in those cases in which the lower animals are not susceptible to the action of the germ: Before any microörganism can be considered the true and sufficient cause of a given disease, it must be shown that the chemical products of that germ are capable of producing the characteristic symptoms and lesions of that disease in an acute form. Thus, Hoffa has obtained from anthrax cultures chemical substances which cause death, preceded by the symptoms of anthrax. Brieger induces tetanus with the ptomaines produced by the growth of the tetanus bacillus; and, moreover, he has isolated the chemical poison from the tissue of a man with lock-jaw, thus overthrowing the criticism made by Banmgarten that it had not been demonstrated that ptomaines are formed in the living body.

Judged by this chemical test, what can we say about the causal relation of the Eberth bacillus to typhoid fever? Does this germ produce any chemical substance which markedly elevates the temperature, such as mydaine, or any which induces local inflammatory and necrotic changes in the tissue, such as cadaverine and putrescine? The typhotoxine of Brieger has no such action. It is true that it is poisonous, but it induces neither the symptoms nor the lesions of typhoid fever. Recent extended researches by Brieger on this point failed to discover in cultures of the Eberth germ any real typhoid poison.

With the above facts in view we certainly can not say that the Eberth germ has been demonstrated to be the true and sufficient cause of typhoid fever. The best that we can do is to give the Scotch verdict of "not proven." Brieger is inclined to the opinion that Eberth's germ plays a secondary rôle in the causation of this disease, and in this opinion I am forced, from the evidence at hand at present, to concur.

Flügge says: "Inoculation experiments with both typhoid dejections and pure cultures of the Eberth bacillus have universally been without success. The few experiments in which a typhoid disease has followed inoculation or feeding have been made with impure material containing other active bacteria. It is known that a group of widely distributed organisms, which, however, are wholly different from the typhoid bacillus, have the power, when injected subcutaneously or intravenously, of producing in animals death, with marked swelling and ulceration of Peyer's patches. To these organisms, undoubtedly, are due the apparently positive results which some authors have supposed to be due to inoculation with the typhoid bacillus."

Since there seems to be very good reasons for regarding typhoid fever as due to mixed infection, it may not be without interest to inquire briefly into some of the experiments made with impure cultures or with germs other than that of Eberth.

All the experiments made by Murchison, Klein and Bahrdt, by feeding with typhoid stools, and those made by Motschutkoffski and Walder, by inoculation with the blood of typhoid patients, were without success. However, Birch-Hirschfeld, by feeding rabbits large quantities of the stools, induced a continued fever, loss of flesh, and diarrhoea. Post-mortem examination showed enlargement of the spleen, swelling of the intestinal follicles, and, in two instances, ulceration of Peyer's patches.

In 1881 Brautlecht reported experiments which he made with organisms obtained from drinking water which had been used by many who subsequently suffered from typhoid fever. Rabbits inoculated with cultures of these germs had some elevation of temperature, lost flesh until they became mere skeletons, and died after from two to eight weeks. Very young animals died within two or three days, after having profuse diarrhoeal discharges. Post-mortem examination showed in the adult animals invariably a severe catarrh of the small intestines and marked enlargement and coloration of the spleen and mesenteric glands. The walls of the intestines were thickened and friable, the mucous membrane swollen, yellowish and reticulated; ulceration was present in some cases, but was generally confined to individual glands. In sixty-nine experiments there was only one in which there was extensive necrosis. Inflammation and abscesses at the point of inoculation were not observed. It should be stated that the inoculations were made subcutaneously. Infection through the stomach was successful in only a few. The first symptoms to appear in these was diarrhoea. Subsequent cultures of these germs lost their virulence.

At the Cincinnati meeting I made a verbal report to this Section upon some work done by Novy and myself, and asked that we be given more time, in order to repeat our experiments. We obtained from drinking water from Iron Mountain, Mich., where there had been a severe epidemic of typhoid fever, a germ which we could not distinguish, by the microscopical appearance, reactions with staining reagents, and growths in gelatine tubes and on potatoes, from the Eberth bacillus.

March 5, 1888, we inoculated three dogs with this germ, taken from a beef-broth culture twenty days old. The germs were washed with sterilized water, then suspended in the same menstruum and injected into the peritoneal cavity, all precautions, such as shaving off the hair, washing first with a solution of bichloride of mercury and

then with alcohol, having been taken; and I may say here that neither at the point of inoculation nor anywhere else in the animals was there at any time any evidence of septicæmia. The dogs were placed in a large cage with a fourth one, which was employed as a control. For some four or five days after the inoculations we took the temperature of the animals daily, but there being no variation beyond the normal limits we supposed the experiment to be negative, and neither of us visited the animal room until the 2d of April, twenty-eight days after the inoculation, when the janitor told us that one of the dogs had died and the two others had grown very thin and seemed to be sick. A post-mortem examination surprised us by revealing very prominently some of the lesions of typhoid fever. The animal was very much emaciated. I asked Drs. Hendricks and Brewer to make the post-mortem, and the following is their report on the same: "The weight of the body was 20 pounds. Upon the abdominal cavity being opened, the mesenteric fat was observed to be pink, with hæmorrhagic spots. The blood vessels of the intestines were found to be highly injected, with numerous points of hæmorrhagic infiltration. On the mesentery near the cæcum were large hæmorrhagic spots. The lower inch and a half of the ileum was distended and covered externally with clotted blood. The mesenteric glands were enlarged to four or five times their normal size, and each contained numerous hæmorrhagic spots. The glands of the vermiform appendix were much enlarged and were pitted in the centre. Under the mesentery of the cæcum was a plastic exudate, almost transparent. The descending portion of the duodenum showed numerous bright hæmorrhagic spots along the line of its junction with the mesentery. Along the upper portion of the ileum the intestine presented a greenish macerated appearance and a soft, pultaceous feel. Air blown into the intestine escaped through the walls at this point. The mucous membrane of the ileum was swollen and Peyer's patches enlarged, but there were no distinct ulcerations. The liver was indurated and of a deep cherry color; weight, 23 ounces. The kidneys were enlarged to twice the normal size and were dark in color. The spleen was enlarged and of a dark purple color. The stomach was contracted and its mucous membrane showed a few hæmorrhagic spots. The lungs were normal and the heart in diastole and free from clots. The thymus and lymphatic glands were enlarged."

I regret exceedingly that we made no attempt to obtain cultures from the mesenteric glands or spleen of this animal.

The next day we began to take the temperature of the other dogs, with the following results:

		No. 2.	No. 3.	Control.
April 3,	2:00 P.M.	105.0	103.8	100.8
April 3,	5:30 P.M.	105.6	104.4	100.4
April 4,	9:00 A.M.	102.8	104.6	100.8
April 4,	3:30 P.M.	103.0	105.0	101.2
April 5,	10:00 A.M.	105.0	103.8	101.4
April 5,	2:30 P.M.	104.0	103.8	101.7
April 6,	9:30 A.M.	105.6	104.8	101.4
April 6,	3:00 P.M.	106.0	106.2	101.6
April 7,	2:30 P.M.	106.8	105.0	101.0
April 7,	7:30 P.M.	106.8	105.2	101.0
April 8,	11:30 A.M.		104.0	101.4
April 8,	6:00 P.M.		104.2	101.0
April 9,	10:00 A.M.		101.0	101.0
April 9,	6:00 P.M.		101.0	101.5

During the night of April 7th No. 2 died. The post-mortem revealed practically the same condition as found in No. 1, save that there was no perforation of the intestines. As is seen from the above figures, No. 3 had no fever on April 9th, and remained in apparent health as long as he was under observation, which was until June 18th.

Twelve other dogs were inoculated April 18th with a subsequent culture of this organism. In four out of the twelve the temperature at the end of the first week registered between 104 and 105 degrees; by the close of the second week it had fallen to 103 degrees, and during the next week became normal and remained so. In each of three others the highest temperature reached was 103.5 degrees. The others were not apparently affected. Not only did the germ thus seem to lose its virulence, but it soon failed to grow in the culture tubes and died out altogether.

Notwithstanding the marked resemblance of our cultures to those of the Eberth germ, I must conclude from the effects obtained that we either had a wholly different organism or an impure culture.

Now, I do not know that these experiments can be considered of any special importance, but, taken together with those of Brautlecht, I think that they give encouragement for further experiments with microorganisms which may be obtained from the drinking water used by those who have typhoid fever.

During the past six months I have spent four or five hours a day upon the study of the etiology of typhoid fever, approaching the work from a wholly different standpoint from that indicated in the preceding pages. I began last December a chemical study of typhoid stools with especial reference to the presence of ptomaines in the same. However, I soon met with great difficulty. In the first place, it was not easy to always have at hand material in sufficient quantity, and although friends practicing where epidemics of the disease existed kindly took the trouble to endeavor to supply me, this difficulty alone was sufficient to cause me to alter my plans. Moreover, the coloring matter present was taken up by my solvents and it proved no light task to exclude them.

I finally adopted the following method: The

stools were received directly from the patient in a sterilized vessel. With a sterilized platinum needle flasks of meat broth previously sterilized were inoculated with these stools. These flasks were then kept at a constant temperature of from  $38^{\circ}$  to  $40^{\circ}$  C. for varying periods of time, after which I attempted to isolate any ptomaines that might be present. Thus, it will be seen that I worked with a mixed culture containing all the germs present in the fæces; the object being to ascertain whether or not the basic substance or substances formed in such cultures would differ from the ptomaine of Eberth's bacillus.

The method of isolating the ptomaine was as follows: After the cultures on meat broth had been kept in the incubator at the temperature of from  $38^{\circ}$  to  $40^{\circ}$  C. for from ten to twenty days they were filtered and rendered feebly acid with hydrochloric acid. I may say here that the cultures were invariably ammoniacal. The acidified filtrate was then evaporated to dryness, or as nearly to dryness as could be done, on the water bath. The residue was extracted with absolute alcohol, the extract precipitated with an alcoholic solution of mercuric chloride, saturated at the temperature of the water bath, the precipitate was collected, washed with alcohol, suspended in distilled water, and decomposed with hydrogen sulphide. The mercuric sulphide was removed by filtration, the filtrate evaporated to dryness on the water bath and this residue extracted with absolute alcohol, the extract precipitated with a solution of platinum chloride in absolute alcohol, the precipitate collected, washed with absolute alcohol and dissolved in distilled water. The aqueous solution was concentrated on the water bath until the platinum compounds began to crystallize out. This aqueous solution contains two or more platinum compounds, but so far I have given my attention to only one of them. This forms in rhombic prisms, which are purified by repeated resolution and recrystallization. For purposes of physiological experimentation, this platinum salt was decomposed with hydrogen sulphide and the filtrate concentrated nearly to dryness on the water bath, when the crystals which I now show you form. This is the hydrochloride of the ptomaine.

The following experiments show the action of this ptomaine: February 6, 1889. An aqueous solution, neutral in reaction, of this ptomaine was injected under the skin over the abdomen at 2:50 P.M. The temperature of the rectum before the injection was  $100.5^{\circ}$ . At 3:35 the temperature was  $102.6^{\circ}$ , at 4:10,  $103.2^{\circ}$ . About this time severe purging set in and continued with intermissions and prolonged straining for an hour. At 4:35 the temperature was  $103.4^{\circ}$ ; at 5,  $103.9^{\circ}$ ; at 5:30,  $104^{\circ}$ ; at 6,  $103.9^{\circ}$ . The temperature was not taken again until 9 A.M. February 7, when it was found to be  $102^{\circ}$ ; at 12,  $101.9^{\circ}$ ; at 6 P.M.,

$100.5^{\circ}$ . Between 2:50 P.M. and 5:30 P.M., or within two hours and forty minutes, the temperature of this animal went up  $3.5^{\circ}$ . The straining and purging were also marked.

May 18, 1889, I gave by the mouth an aqueous solution of the crystals to a dog which weighed 15 lbs. The rectal temperature before the administration of the poison was  $101^{\circ}$ , the time of administration, 3 P.M. At 3:15 retching and vomiting set in and continued at intervals for more than two hours. At 3:30 the temperature was  $103^{\circ}$ , an elevation of  $2^{\circ}$  within one half-hour. At 3:55 the animal began to purge. The first discharges contained much fæcal matter, but the subsequent ones were watery and some of them contained mucus plainly stained with blood. At 4, the temperature was  $103.5^{\circ}$ , and remained the same at 4:30. The animal was not seen again until 10 A.M. the next day, when its temperature was  $100.5^{\circ}$  and recovery seemed complete.

I have records of other experiments with this ptomaine, but as they are repetitions of the above in general, I will not detail any more at present.

I should not place any great stress upon the elevation of temperature were that the only symptom, but when taken with the gastro-intestinal disturbance I think that I have some reason for hoping that the discovery of this ptomaine may prove of value in elucidating the etiology of typhoid fever. Of course, further experimentation is necessary. It remains to be seen whether or not typhoid stools invariably contain germs capable of producing this chemical product, also whether or not the same germs are contained in normal stools or in those of any other disease than typhoid fever. Moreover, I hope by means of making plate cultures to determine whether this ptomaine is the result of the activity of a single germ or of two or more microorganisms. I may say that the stools used in these experiments were from undoubted cases of typhoid fever and from three widely separated outbreaks of the disease.

Some of the conditions influencing the formation of this poison may be of interest. It was found most abundantly when the cultures were kept at a temperature of  $40^{\circ}$  C. for a period of ten days. After this time the amount of the yield grows less, though I have found traces after twenty days. I obtained larger quantities from cultures made on pork broth than from those made upon beef broth, though the poison was never absent from the latter. From 6 quarts of pork broth I obtained as the greatest yield nearly 2 grams of the platinum compound. Though I have made several partial ultimate analyses of the platino-chloride I am not yet ready to give a formula for this base, nor do I care to propose a name for it at the present.

The platino-chloride crystallizes in fine rhombic prisms and the hydro-chloride in the red needles which I have shown you. The red color seems

to be inherent to the substance and not due to impurities. The hydro-chloride obtained from the decomposition of the mercury compound has the same color as that from the platinum compound.

The mercury and platinum compounds are insoluble in absolute alcohol, soluble in water. The hydro-chloride is soluble in both water and alcohol.

DR. WELCH said that he must protest against accepting one condition which Dr. Vaughan formulated, viz.: that before we admit that a given microörganism is the cause of a disease we must isolate from cultures of this organism chemical products which are capable, by inoculation or feeding, of producing the symptoms of this disease. It is certainly an important addition to our knowledge of a disease to become acquainted with such chemical products, but this is not essential to a belief in the causative agency of a specific microörganism. If Dr. Vaughan's condition be accepted as an essential link in the chain in proof, then we have not sufficient evidence that many recognized infectious organisms, such as the spirillum of relapsing fever, the bacillus of leprosy, or even the tubercle bacillus, are the causes of their respective diseases. From our present knowledge we are justified in believing that a microörganism which is invariably associated with a disease, which is found in the lesions of the disease and in situations which explain the symptoms and lesions, and which is never found except in association with the disease, must be regarded as the cause of the disease. When in addition to this we are able, by experiments on animals, to reproduce the disease by inoculation of pure cultures, this additional proof is most welcome, but in many infectious diseases we cannot furnish this last method of proof, either because we have not been able to isolate and cultivate the suspected organism, as is the case with relapsing fever, or because animals available for experiment are not susceptible to the disease, as seems to be true of typhoid fever and cholera. For this reason Koch has stated that it is not absolutely necessary that we reproduce the disease experimentally in animals by inoculation before we admit that a given organism found associated with a disease under the conditions stated is the specific cause of the disease. The evidence Dr. Welch believed to be conclusive that the typhoid bacillus is the specific cause of typhoid fever.

Dr. Vaughan's emphasis of the necessity of demonstrating the chemical products of pathogenic microörganisms before we accept their etiological significance, is based upon the assumption that infectious organisms produce their disastrous effects solely by their chemical products, but this assumption is quite unwarrantable. In fact, there is reason to believe that, while some pathogenic organisms act by chemical products, others do not so act.

As Dr. Vaughan himself is doubtful as to the interpretation of his experiments on dogs, Dr. Welch is not inclined to attribute to them any bearing upon the etiology of typhoid fever, without further information than we now possess.

Dr. Vaughan is to be congratulated upon the isolation from typhoid stools of a definite crystalline substance with such interesting properties; but, as Dr. Vaughan himself has stated, it will be necessary to make control chemical observations with diarrhoeal or other stools not derived from typhoid patients, before the relation of this substance to typhoid fever becomes clear.

DR. TYSON believed in the truth of the original idea that to establish the specific nature of an organism it is necessary to find it in the blood, that it shall be capable of producing the disease in another creature, and that it shall be here also found. This would seem at least conclusive proof. It seems much a matter of mental constitution how much of these views we accept.

DR. WILSON said that Dr. Vaughan had not claimed that his discoveries had been definitely established. He should certainly be thanked for the manner in which he is working out the difficult task which he has undertaken. Our knowledge of infectious diseases has been acquired by slow stages. Nothing has been revealed by the clinician; scarcely more by the pathologist. The bacteriologist has brought our knowledge a tremendous stadium forward. But there are wide lacunæ that are still obscure and waste. We should be very grateful to the bacteriological chemist for his efforts to help us. There is uncleaned ground, and every just hypothesis, no matter how repugnant, should be gratefully welcomed.

DR. VAUGHAN, in closing the discussion, said: I will give my attention wholly to the criticism of Prof. Welch. Prof. Welch says that the first of Koch's rules is all that is necessary in order to prove that a given germ is the cause of a disease. In other words, because you find Eberth's germ in every case of typhoid fever, it must be the cause of that disease. He does not think that all the failures to induce the disease by inoculation with this germ are of any significance. When Koch first promulgated his four rules and pronounced that they must be complied with before the causal relation of a germ to a disease should be considered as demonstrated, the scientific accuracy of such a demonstration won the confidence of the medical world. Now, Professor Welch says that three of these four rules are unnecessary. He claims that the presence of the Eberth germ in the altered tissue of typhoid tissue is a proof that these germs cause typhoid fever. How does he know that the presence of the germ is the cause and not the result of the disease? He reaches this conclusion by reasoning from analogy. This kind of reasoning may have its value, but it is not scientific. Sup-

pose that an inhabitant of some far off planet should, by means of optical instruments, be able to discern the inhabitants of a certain portion of this globe. Suppose that the portion of this globe which should fall under his observation to be the frigid zone. Here he would find the inhabitants living in houses built of snow and ice, and reasoning by analogy he might conclude that all the inhabitants of the earth live in houses of this kind. The reasoning of Prof. Welch is just as unscientific as that in the supposed case of our planetary observer. Condensed, his reasoning would be about as follows: 1. The bacillus of consumption is found in every case of consumption and the Eberth germ is found in every case of typhoid fever. 2. The bacillus of tuberculosis has been demonstrated to be the cause of consumption. 3. Therefore, the Eberth germ is the cause of typhoid fever.

### RAYNAUD'S DISEASE.

*Read in the Section of Practice of Medicine, Materia Medica and Physiology, at the Fourteenth Annual Meeting of the American Medical Association, June, 1889.*

BY G. M. GARLAND, M.D.,  
OF BOSTON.

Death and mortification of a member of the living body, without external injury, were formerly classified under the one head of spontaneous gangrene and considered mysterious visitations. It was thought obstructions to the circulation might be the cause of these strange conditions, and on the other hand, Quesnay (1749) was the first to suggest that gangrene might result from disturbances of nerve function, and he endeavored to establish this theory by nerve sections upon animals.

The matter rested here for many years, until, in 1832, V. François revived interest by an attempt to prove that gangrene may be produced by the influence of the nerves upon the blood-vessels. Then came Virchow's celebrated elucidation of the difficult problems of thrombosis and embolism and his declaration that the term *spontaneous gangrene* was rapidly falling into disuse with the clearer understanding of the arterial and venous service. Virchow found cases, however, which did not fall into the category of "arterial obstruction," and notable among such, the gangrene of ergotism. Moreover, there appeared now and then rare forms of gangrene wherein symmetrical parts of the body were affected. This eccentric group of cases received special attention from Zambecco (1857), Racle (1859), Samuel (1860) and Raynaud (1862).

In recognition of the valuable work of Raynaud in collecting together and critically analyzing all the reported cases of *symmetrical gangrene*, and thereby differentiating a distinct type, this affection has been termed "Raynaud's Disease." In

his famous thesis (1862) Raynaud says: "I propose to demonstrate that there exists a variety of dry gangrene affecting the extremities which it is impossible to explain by a vascular obliteration—a variety characterized especially by a remarkable tendency to symmetry, so that it always affects similar parts, the two upper or lower limbs, or the four at the same time. Further, in certain cases, the nose and the ears; and I hope to prove that this kind of gangrene has its cause in a vice of innervation of the capillary vessels." Weiss defines the disease as a neurosis which "manifests itself through various vasomotor, trophic and sensory disturbances, and acquires a peculiar type through a gangrene which appears very often on symmetrical parts of the hands and feet, and more rarely upon other parts of the body."

All cases of this disease do not advance to gangrene, and therefore Raynaud has divided the trouble into three stages as follows:

The first stage is termed *local syncope*. Certain parts of the body, more often the toes and fingers, turn to a waxy, cadaverous color, and the latter are familiarly called "dead fingers—*digiti mortui*." The sensibility is notably diminished and movement is hindered. The skin becomes wrinkled. Subjectively the patient may have simply an indescribable feeling that something is going wrong in the part, or there may be a sensation as if the parts were going to sleep, or light shooting pains may occur. The temperature of the parts affected is notably lowered, as shown by the following tables by Mills:

#### MILLS' OWN FINGERS.

Right thumb, 93.8° F.; left thumb, 93.2° F.  
Right index finger, 92° F.; left index finger, 92.3° F.  
Right middle finger, 92.8° F.; left middle finger, 92.7° F.

#### THE PATIENT'S FINGERS.

Right thumb, 85.1° F.; left thumb, 86° F.  
Right index finger, 86.9° F.; left index finger, 84.2° F.  
Right middle finger, 85.1° F.; left middle finger, 87.8° F.

The return to the normal state is accompanied by light prickling sensations. The only illustration of this stage which I have seen is in the person of my own uncle, an old gentleman of 78 years. During cool weather for the last few years, he has had great difficulty in preventing several of his fingers from freezing. Whenever he goes out of doors, these fingers become like dead members and he must resort to vigorous rubbing to restore them to the normal.

The second stage is termed *local asphyxia*, and consists of "recurrent paroxysmal attacks of blueness of symmetrical extremities of the body, with return, during the intervals, to a perfectly normal condition" (Barlow). This stage may be sequent to the first or it may develop directly from the normal condition. The part turns dark red, and then gradually blue and black. Sometimes the color is a lead gray or slate. The pain is moderate and may require opiates, but it is not equal to

the pain of gangrene. The return of the color and local temperature to normal may be very rapid, as seen in the following table of Hoesslin:

RIGHT HAND.			
6:55	o'clock,	temp. 24.5° C.	Cyanosis still marked.
7:10	"	29° "	Cyanosis disappeared.
7:15	"	33.8° "	Hand scarlet red.
7:18	"	35° "	
7:21	"	35.5° "	

The following case by Dr. Barlow will serve to illustrate this phase of the disease:

Girl 5 years old. The whole of the right foot and ankle and the leg for a distance of 3 or 4 inches up had become within a short time cold and of a nearly uniform grayish color. The child whimpered a little with pain in the foot and did not like to have it handled much. On the dorsal surface of each forearm there was an area of perhaps 3 inches in length, of ill-defined blueness and coldness. This slight blue area was more marked on the right than on the left side. The blueness passed away within an hour or two. Two days after, the child had another attack in the presence of Dr. Barlow. There was slight blueness and coldness of the left foot, and the child whimpered a little but was able to walk across the ward with a slight limp, and the foot became natural again in less than half an hour and she had no further trouble. She was out the next day. The attacks were confined to cold weather but came on indoors occasionally, and sometimes commenced with gaping and complaint of sickness.

The third stage is the *symmetrical gangrene*, so called, which usually develops out of the asphyxiated condition. A person may have numerous attacks of local asphyxia and recoveries before gangrene occurs, or the third stage may follow the first attack. The gangrene is usually of the dry, mummified type, and may go on to spontaneous amputation in ten days. Raynaud says he has a choice collection of gangrenous corporate members in his office. Oftentimes, however, the gangrene is of the moist, sloughing character, as will be seen in the cases cited. The pain is sometimes very severe and lasts for several days, and the process of healing is very slow. Three or four months may be consumed in restoring the skin, and then crusts of epidermis may continue to form and detach for more than a year.

The following case was seen by me in February last:

Peter L., a lawyer, 32 years of age. Had always considered himself well, except for the trouble in his feet. He came of rugged English stock, and he said that his grandfather fought on the English side at the battle of Bunker Hill. In 1886 he was called up one cold winter night, and was driven several miles in an open sleigh to draw up a man's will. On returning, he found his right foot slightly frost bitten. A vigorous rubbing restored the circulation, however, and he thought no more of it.

A few days after, he noticed a change in color of one of the toes, and then a superficial sore formed. This gradually healed and then a sore came upon another toe; this sort of thing continued for a year, when he noticed similar appearances upon the toes of his left foot. During the three years that had elapsed at the time I saw him, the individual attacks had so overlapped each other that he had never known a time when his toes were entirely free from these sores. Each new attack was ushered in by a severe pain which lasted for a few days. By wearing old shoes with the toes cut away, he was able to attend to his business. The gangrenous ulcers had usually been so superficial that they left no scar on healing, but there was one large, conspicuous cicatrix, upon the under surface of the right big toe, where the recent loss of tissue had been considerable. At the time of my visit the man appeared as follows: He looked very anæmic and feeble. He had been suffering from a severe cold and a slight pleurisy, of which there remained only a few friction rubs. He was sitting in an easy-chair with his feet supported in front of him. There was one toe on each foot with its tip gangrenous. One or two other toes were deeply asphyxiated. The right foot and leg were swollen, and at times turned blue. There was no apparent diminution of sensation anywhere. He could feel the lightest touch on all the toes. The urine contained no sugar, but revealed evidence of Bright's disease, from which trouble the patient died in May.

Some writers have said that Raynaud's disease is not in itself fatal, but the following case by Dr. T. B. Adams shows that it may cause death:

The patient was a poor, feeble-looking child, with sallow complexion. Her breath had a distinctly gangrenous odor on entering the hospital. The feet and lower third of both legs were perfectly black and gangrenous. The toes were shrivelled up and dry. An irregular line of demarcation existed about the junction of the middle and lower third of both legs, and the suppuration was already considerably advanced. The left leg was more extensively affected than the right. For three months previous the child had been subject, in the forenoon of every day, to attacks of arrested circulation, with imminent gangrene, upon the ears and cheeks and on one or both hands. Ears or cheeks were never observed to be affected on the same side as the hands, but alternately. The child entered the hospital March 11, and died from exhaustion April 7.

#### THEORIES.

As to the nature of the disease, I find that opinions are widely variant and the evidence incomplete. Raynaud believed that all three stages were due to perverted innervation of the arterioles, and he has written a number of articles to defend this theory. Among other facts, he has noticed

that some patients are affected by an obscurity of vision during the local peripheral discoloration, and in such cases he thinks he has detected a contraction of the retinal vessels, which would harmonize with his theory of arterial spasm. Other writers, while they allow that arterial spasm might account for the white fingers, do not believe that such spasm could be sufficient to produce gangrene, and therefore they think that the trouble is a tropho-neurosis or an impairment of the nutritive functions of the cells themselves, irrespective of the arterial supply.

O. Weber advanced the theory that the color changes in local syncope were due to a spasm of the muscular fibres in the skin itself, while Weiss thinks that the local asphyxia is due to a spasm of the veins of the part. These theories, however, have received no credence beyond their own authors.

Pitres and Vaillard report a case in which at the post-mortem they found parenchymatous degeneration in the nerves of the part, *i. e.*, a local neuritis which extended for some distance outside of the dead tissue. They said the changes observed were not such as ordinarily occur in thrombotic gangrene, and which are due to an extension of inflammation from neighboring tissues, and they think that their case was a neuritis. On the other hand, Recklinghausen reports a case, wherein he found an endoarteritis obliterans in the arterioles of the gangrenous member. It is evident, therefore, that similar conditions may be induced by dissimilar processes, and that many cases which are to-day grouped under one heading must be further differentiated before we can reach a satisfactory solution of the essence of Raynaud's disease.

#### ETIOLOGY.

Numerous accidents and insults have been quoted as productive of symmetrical gangrene. In the case reported by the reader, frost bite seemed to be the provoking cause in the right foot. Syphilis, malaria, abuse of morphine, heredity, have all been advanced as causes of this disease. Hochenegg says that various disturbances of nutrition may provoke symmetrical gangrene, as

- a. Excessive physical exertion.
- b. Chlorosis and chronic anæmia.
- c. Chronic inflammatory and acute infectious diseases.

Symmetrical gangrene is also often observed with Bright's disease and diabetes. Goldschmidt describes a case in which gangrene was associated with scleroderma, and he believes, with a number of others, that Raynaud's disease is only one phase of scleroderma. On the other hand, local syncope not infrequently accompanies attacks of paroxysmal hæmoglobinuria, and Dr. Druitt describes such an association in his own person.

During an attack, he would fall into a condition resembling the algid stage of cholera. Then a patch on his cheek or his nose or his fingers would grow cold and white. He also had such localized syncopal spots with attacks of jaundice, supposed to be due to spasm of the hepatic arteries. He believed in the angio-neurosis theory.

#### TREATMENT.

The treatment of any stage of Raynaud's disease is extremely unsatisfactory. The *digiti mortui* recur again and again during the cold months, and nothing can prevent it. The most one can do is to keep the parts from actually freezing during their bloodless condition. The local asphyxia is equally obstinate. Some persons never have but one attack, while in others it recurs at irregular intervals. Raynaud and Barlow think that they have mitigated and shortened individual attacks by the use of galvanism, but they both agree that this does not prevent recurrence. At first, Raynaud applied the galvanism along the spine, on the supposition that the seat of the disease was central, but he soon found that peripheral applications worked equally well. Internally, various remedies have been employed with invariably negative results. Nitrite of amyl has no power to abort an attack of local syncope. Iodide of potash and nitro-glycerine are equally impotent.

In closing this paper, it will be of interest to note a peculiar affection described by S. Weir Mitchell, and termed erythromelalgia or red neuralgia. This is a painful affection of the extremities, generally of the feet, and is accompanied by a flushing and mottling of the parts upon slight exertion. It may attack the toes symmetrically and progressively. There is intense pain in the toes and bottoms of the feet, which is relieved by rest and the horizontal position. The trouble occurs oftenest in males, between the ages of 20 and 40 years. It is not amenable to treatment.

### ON THE VALUE OF ANTISEPTIC TREATMENT, AND PROTECTION FOR THE MEMBRANA-TYMPANI, IN PERFORATIONS THE RESULT OF OTORRHOEA.

*Read in the Section of Laryngology and Otolaryngology, at the Fortieth Annual Meeting of the American Medical Association, Newport, R. I., June 25, 1889.*

BY LAURENCE TURNBULL, M.D., PH.D.  
OF PHILADELPHIA, PA. AURAL SURGEON TO THE JEFFERSON MEDICAL COLLEGE HOSPITAL.

It will not be necessary at this late date, to advocate or dwell at length upon the great value, nay, absolute importance, of antiseptic surgery. Its latest triumphs and most brilliant results, have been shown in brain surgery. It is not only possible to reach and drain abscesses in the temporo-sphenoidal lobe of the cerebrum, but it

is considered possible to save life by opening into the cerebellar fossæ and removing pus from the neighborhood of the lateral sinus. The antiseptic treatment of chronic purulent disease of the middle ear was a natural sequence, and was soon followed by the use of boracic acid in powder and solution, and still later by the superior antiseptic agent, bi-chloride of mercury in solution; then the use of antiseptic wool and gauze, with the protecting agency of oiled silk as "protectors" and artificial membranes which act so as to prevent the entrance of diseased germs from the air. As long as there is a discharge, open Eustachian tube, wash with the solution, then apply the gauze, and when the suppuration has ceased employ the oil silk, or rubber, cut about the size of the membrane applied to the perforation, and when the parts are very dry, use the antiseptic solution or equal parts of ether and glycerine.

Some of the causes preventing the cure of a discharge from the ear, are:

1. The perforation may be so small that injections cannot be made to enter or penetrate the tympanic cavity. These openings must be enlarged.

2. Concealed polypoid growths. These must be snared or touched with chromic acid.

3. A circumscribed area of carious bone involving the ossicles, or attic or mastoid antrum. They are to be removed through the mastoid.

4. A fistulous canal, caused by necrosis of the bone, which forms the upper and posterior wall of the osseous external auditory canal. This is to be kept clean by the mercurial solution; and carious bones or granulations are to be removed by the sharp spoon.

*In Non-Closure of Perforations of the Membrana Tympani.*—Various attempts have been made to cover perforations of the membrana tympani. Berthold and others attempted to close these perforations by grafts of skin from the arm. These proved too thick and difficult to adapt to the edges of the perforation. He then abandoned this for the lining membrane of the chicken's egg, which is known to be vascular and capable of resisting putrefaction for some time. A fresh egg only must be used, and a suitably sized piece applied to the perforation by means of an especial canula.

Dubousquet substituted for the last-named membrane bits of interdigital skin from the frog's foot. Baratonx has used the *nictitating* membrane of the frog's eye for the same purpose with good results. He also has used it to resolve mucous membrane in certain forms of rhinitis.

*Perforations in Young Children* are more difficult to treat. Inspection often fails to reveal a perforation, on account of the difficulty of getting a full view of the membrana tympani. This is due to the position of the drum-membrane rela-

tively to the meatus. In the infant, at birth, the membrana tympani lies almost horizontally, and as a consequence, the walls of the meatus lie in contact. At this age the osseous meatus is almost entirely wanting.

In order to gain a view of the membrane in infants, it is necessary, instead of straightening the meatus by drawing the auricle upwards and backwards, as is done in the adult, to draw the auricle downward and outward, and in using the speculum to look upward.

By way of illustration I quote two cases of antiseptic treatment in *otitis media chronica*, with perforation, long continued discharge and noises, entirely relieved by the use of antiseptic covering, as a means of protection from the air.

Nov. 3, 1888. Mrs. A. C., æt. 55, from the interior of Pennsylvania, has been under treatment for perforation in both ears, has a tendency to rheumatic gout, great depression, and heart enlargement from long continued nursing, heavy lifting, etc.

To relieve noises, a 1 per cent. solution of nitro-glycerine was directed, also lithiated potash for rheumatic pain. The ear was cleansed, and then treated with ointment of the yellow oxide of mercury and morphia.

For the slight discharge: Applied antiseptic protectors (gauze sterilized by a solution of mercuric bi-chloride, 1-4000) in both ears. No pain was experienced except in the nape of the neck, for which bromide of sodium 30 grains at bedtime, was prescribed, and over the mastoid painted with tincture of iodine.

It is not necessary to enter into detail, save to say, that one "protector" remained intact for months. No inconvenience resulted, and no noises were heard in left ear, and but slight fullness remained in right. The use of the bromide was continued; so, also, the local application of tincture of iodine.

In the case of Mrs. Robert M. I., æt. 30 years, an otorrhœa (*otitis media chronica*) with three perforations in right ear and two in the left; has had more or less discharge for thirty years, and has been under the best of care in New York and Philadelphia; but only received temporary benefit. By the use of equal parts of glycerine and tinctura ferri seq. chl. to the throat and antiseptic solution to the ear, the perforations in the right ear closed. There still remain two perforations in the left ear, which have become free from discharge; these were covered with antiseptic protectors, and now the patient is much improved in her hearing, no pain and no discharge. I might occupy your time in details of at least fifty similar cases, of all ages, occurring within the last two years, some of them of the most severe and protracted character, which have eventually been either cured, or else so protected that they were no longer distressing to the patient. The great

secret is the use of the antiseptic, and excluding of foul and contaminated air, which is all the while charged with injurious material, which irritates the delicate mucous membrane, by simple contact, or generating bacteria, and micrococci of various forms. This poison causes not only grave disease of the middle ear, but also of the brain, entering the blood, and being carried from thence to the lungs ultimately, developing phthisis and other constitutional diseases, more especially in the young and delicate. To prevent such results, I always resort to constitutional treatment, the syrup of the iodide of iron for children, and for adults, to "Chapoteant's morrhinol," or active principle of cod-liver oil, and the elixir of the valerianate of strychnine.

The "protectors" or artificial membranes have another advantage in that they in the majority of cases, while assisting the healing of the perforation, improve the patient's hearing by support and pressure on the ossicles.

I would recommend thorough and complete antiseptis in all cases of otorrhœa. The cleansing must be done by skilled hands, and just so soon as all products of fermentation or decomposition are removed, then the healing process will commence, and "Dame Nature" will complete the cure.

I use the term "protectors," because, be the substances used to exclude noxious air or vegetable or animal life, what they may, they do not always act as artificial membranes (*membrana tympani*), and if in using such a protector of inert material or of animal tissue, we can secure the double purpose of antiseptic protection and augmentation of hearing power, we have every reason to be satisfied.

In conclusion, I should urge treatment in every case of otorrhœa with the idea of not only preventing all discharge, but of furnishing protection, at all times, to the mucous membrane of the tympanum; which protection, in the form of a mechanical protector, in nine cases out of ten, practically acts as an artificial *membrana tympani*.

1502 Walnut Street.

## RELAXATION AND MANAGEMENT OF THE PERINEUM DURING PARTURITION.

*Read before the Golden Belt District Medical Society of Kansas, July 4, 1889.*

BY WILLIAM B. DEWEES, A.M., M.D.,  
OF SALINA, KAN.

(Concluded from page 355.)

This brings us to the second grand division of the subject. Recognizing the natural law, that:

1. Normally, every perineum will properly dis-

tend to allow the exit of the child, leaving all the tissues intact.

2. To obtain a normal dilatation of the perineum, sufficient to allow the exit of the child, preserving the integrity of the tissues, is the highest object attainable.

It becomes the most solemn duty of the obstetrician to conscientiously endeavor, by a studious scientific inquiry, to seek and remove—as far as lies within his knowledge and skill—the *real cause* of the defective distensibility of the soft parts; to which factor, science and experience alike teach us, parturient lacerations of the perineum must be so largely ascribed; if he would do the best thing, in the best way, to prevent rupture when the head is down on the perineum.

Contemplating this subject, I have endeavored to seek in nature the phenomena of the *true doctrine*. Lest I fail to acquit myself of a just consideration, let me assure you of my entertaining no particular attachment, nor prejudice, to any opinion of the authorities respecting it. This circumstance gained me the advantage of an unbiased and impartial examination of facts, from which I drew my conclusions with a deference to reason. Thus, for more than fourteen years, my earnest practical attention has been devoted to this subject, at every opportunity presenting. Being called to a woman in labor, and finding her in the first stage, I invariably endeavor to ascertain, as early as possible, whether there is any disposition in the soft parts to yield, as labor advances, and whether it be complicated with any mechanical obstruction, such as indurations, scirrhus, contractions, adhesions, tumors, malformations, etc. The case proving to be one within the scope of this paper, and bearing in mind the two general causes of laceration, to wit:

*First*.—The undilatable character of the perineum and adjacent soft parts, chiefly the vulva and anterior perineum; and

*Second*.—The wrong direction in which the uterine forces operate.

The indications for relaxation and management are very clear, viz.:

*First*.—To remove all exciting and aggravating causes, and to diminish, by direct or indirect measures, the vascular and nervous excitement, both general and local.

*Second*.—To guard the perineum, by guiding, controlling or aiding, with artificial means (chiefly the hands and forceps) the uterine forces so as to operate properly.

With my mind thus refreshed, I keep the lying-in chamber quiet, cool and well ventilated; allow the patient none but semi-solid and liquid, easily digestible food; limit the company to the fewest number consistent with the requirements; confine conversation to suitable and agreeable topics; quiet the patient's anxieties with presenting the most favorable prospect in accordance with the

truth and duty; and constantly direct every detail tending to better her physical comfort. Thus removing all exciting and aggravating causes, I proceed to the consideration of the means which proved most efficient, to diminish vascular and nervous excitement, thereby obtaining normal distensibility of the tissues.

Ordinarily my first step is a rectal enema of *hot water*, 120° F., ranging in quantity from 1 to 3 pints, administered during the interval of pains, with the patient lying in the left lateral semi-prone position; the water allowed to be evacuated only when it can no longer be retained. This may be repeated several times, *pro re nata*. The first injection will usually be voided in a few minutes, doing scarce more good than bringing away the accumulated fæces. However, a second one, administered immediately after, will be easily retained from fifteen to thirty minutes and even longer. During the pains *hot water*, from 120° to 130° F. (as hot as the patient can bear comfortably) wrung out in clean cloths, applied to the distended perineum and vulva. Water used *hot* as here indicated, has proven of great value in my hands. In the majority of cases of "vital rigidity" its therapeutic value was chiefly manifested, in order as follows: By giving great comfort to the patient, in producing a general warmth and quietude; by allaying both vascular and nervous excitement; by promoting labor pains; by inducing rapid relaxation of the os uteri, vagina, perineum and vulva; and in many instances lessen suffering and shorten labor very materially. The minority of cases of this class will, however, not yield to this treatment; hence we have to resort to other means following this step, in our endeavor to successfully aid this physiological process to its safe termination.

This brings us now, to carefully notice the two distinct general classes into which these cases are naturally divided, in order that we may the more intelligently comprehend the indications for treatment in each class respectively, lest we should find ourselves guilty of error, with serious consequences to mother or child, or both, as well as to our own reputation. These two general classes are:

*First*.—Those who are mainly of a "*sanguine temperament*"—plethoric, of firm fibre or possess much muscular power, and who are generally composed but irritable.

*Second*.—Those who are mainly of a "*lymphatic temperament*"—anæmic, of lax fibre or possess but little muscular power, and who are generally nervous and irritable.

The two remedies paramount are *blood-letting* and *chloroform*. Venesection is the sheet-anchor in the first, while chloroform is equally so in the second, of the two general classes of these cases.

Were these grand distinctions more generally recognized and these rational means properly em-

ployed, we would learn much less frequently of the serious results occurring from rigidity, than the present statistics are forced to show. This is, however, not a new—though it be a much neglected—doctrine, for we learn that as early as 1860 Hodge<sup>76</sup> wrote: "The testimony of practitioners seems to prove very positively, that all the rigidity which depends on *muscular excitement*, often so great as to cause spasms, will be relieved by anæsthesia; the tension disappears, and the tissues become relaxed; but where the rigidity depends more upon *vascular excitement*, or upon any physical condition of the parts, there is comparatively little or no relaxation."

Experience has taught us, however, that the distinction drawn by Hodge, though proper, is too scarce in detail to serve as a reliable safeguard to all, when occasion demands discrimination at the bedside. Therefore I beg leave to submit the following differentiation as to the employment of these means, as well as the similarity in result obtained:

## BLOOD-LETTING.

## CHLOROFORM.

- |   |   |
|---|---|
| <p>1. Blood-letting (venesection) is indicated and should be employed only in the first of the two general classes of these cases.</p> <p>2. To be effectual must be copious.</p> <p>We have not observed in any instance, that a less quantity than 20 ozs. has produced any great effect upon the rigid tissues at the pelvic outlet; but in those cases where 20 to 40 ozs. were taken, it instance, that any great effect was frequently acted like a charm in producing upon the rigid tissues producing rapid dilatation of the by this agent, unless continued to parts. Hence we have often repeated the operation, with the most happy results, when no effect was manifested from the first as to stimulate the uterine contractions. The uterine contractions when weakened from prolonged efforts, in these cases, have invariably been stimulated into healthy activity following this procedure.</p> <p>3. Thus employed, at the time of parturition, is a safe, easy and effectual means of lessening the suffering; relaxing the rigidity of the perineum and adjacent soft parts; and often shortens labor very materially.</p> <p>4. It may be objected to this practice, that copious blood-letting would occasion syncope, whereby the uterus might lose its power of contraction and consequently there would be an inability to expel the fœtus. Such an accident we believe could not occur unless considerable more blood than necessary was taken, since we have the following two laws, as well established factors in science:</p> <p><i>First</i>.—That a large quantity (20 to 40, and even 60 ozs.) of blood,</p> | <p>1. Chloroform is indicated and should be employed only in cases of the second class.</p> <p>2. To be effectual, must be administered moderately and only during the period of uterine contraction; but at no time, to total unconsciousness and insensibility.—or to complete anæsthesia.</p> <p>We have not observed in any instance, that any great effect was produced upon the rigid tissues by this agent, unless continued to parts. Hence we have often repeated the operation, with the most happy results, when no effect was manifested from the first as to stimulate the uterine contractions. The uterine contractions when weakened from prolonged efforts, in these cases, have invariably been stimulated into healthy activity following this procedure.</p> <p>3. Thus employed, at the time of parturition, is a safe, easy and effectual means of lessening the suffering; relaxing the rigidity of the perineum and adjacent soft parts, and less often shortens labor.</p> <p>4. It may be objected to this practice, that chloroform anæsthesia would occasion cerebral anæmia, whereby the uterus might lose its power of contraction and consequently there would be an inability to expel the fœtus. Such an accident we believe could not occur unless considerably more chloroform than necessary was administered, since we have the following two laws, as well established factors in science:</p> <p><i>First</i>.—That chloroform may be administered periodically in</p> |
|---|---|

<sup>76</sup> Hodge's System of Obstetrics, p. 427—remarks on perineum.

may be drawn from the arm of small quantity (from  $\frac{1}{2}$  to 1 dr.) the parturient woman, without injury to the mother or child.

*Second.*—That it is not necessary to bleed until fainting is induced, in order to effect a relaxation of the parts or to restore the uterus to its normal action.

to the parturient woman, without injury to the mother or child; but administering it continuously or to complete anesthesia, is always fraught with great danger.

*Second.*—That it is not necessary to administer the anæsthetic continuously nor to complete anesthesia, in order to effect a relaxation of the parts, or to restore the uterus to its normal action.

Speaking of the wrong direction in which the uterine forces operate, as a frequent cause of lacerations, we can do no better than quote Hodge,<sup>77</sup> who teaches that: "Perforations occur frequently, because the whole uterine forces are directed chiefly upon the posterior perineum, as is observed in occipito-posterior positions of the vertex, in some positions, it is said, of the shoulder presentations, but more especially in cases of deformed pelvis, especially where the sacrum is too straight, or too near the pubis, or where the os coccygis is ankylosed or turned too much inward, and also where the rami of the pubis and ischia approximate too closely, making the arch of the pubis too angular. In all such instances, the proper extension of the head cannot occur, and it is determined inordinately against the floor of the pelvis." Here, we repeat, the indications for management are "to guard the perineum by guiding, controlling or aiding, with artificial means, the uterine forces, so as to operate properly."

This is chiefly to be accomplished by the *hands* and *forceps*. But it must be remembered that no one definite procedure can be given by which all the different conditions occurring from this cause can be equally successfully corrected. Therefore it behooves every conscientious physician who undertakes to direct the parturient process, to carefully, thoughtfully and earnestly study the character, condition and, so to speak, the individuality of each case of labor to which he may be called, if he would intelligently "follow his guide and fear no evil," and obtain all possible success in preserving the integrity of the tissues. Nevertheless, how often do we find physicians who are in the habit of making an examination by the vagina in order to ascertain the progress of labor, without paying any attention to the individual state of either the *physical* or *nervous* condition of the patient, and idly sitting by the continued useless sufferings, awaiting the "labor's own time for termination." I have seen—one of my earliest cases, while faithfully carrying out directions "to wait at my post," a consulting physician draw a dead child through a ruptured perineum—a child lost, and the perineum separated. How much better to have applied the forceps in time to save the child perhaps, and with proper precautions the perineum, sparing the mother all that long agony. Case No. 4 of this paper is likewise in point.

Forceps delivery not being within the province of this paper, I shall confine myself, in my concluding remarks, to the use of the hands. Of the various foregoing methods as advised by the numerous authorities on this subject, I have myself found the greatest benefit from those as practiced by Goodell, Playfair and Reamy.

However, neither of these methods enabled me to secure all that it seemed possible to obtain in this direction, consequently—"Find thou the method, and the means prepare." I have endeavored to find the means by which the greatest possible good could be obtained, and take great pleasure to submit for your consideration and criticism the following management, which proved more beneficial than any other, tried with my hands:

When I find the head fairly engaged in the pelvis, and advancing with each pain, the tissues rigid and unyielding, I take my seat by the patient's bed and, having lubricated my left thumb, or the two first fingers of my right hand, I introduce either into the vagina, by hooking over the fourchette and posterior commissure, and at the outset of a uterine contraction draw back the perineum firmly but gently toward the coccyx, as far as is possible, relaxing the tension gradually as the contraction lessens; repeating the same procedure at each ensuing contraction, till I can draw back the perineum with slight effort. During the interval of contractions, I foment the parts with hot water ( $120^{\circ}$  to  $130^{\circ}$  F.) wrung out in clean cloths (towel or napkin), and also freely using inunctions of lard. Thus I *tire out* the contractility of the muscular structures, and produce relaxation, as well as a consequent disposition of the tissues to dilate. In most cases so treated the perineum is in the least possible danger; and in this connection, may I be permitted to ask—Does it not seem anomalous, that the perineum should be expected to dilate on such a short notice, namely: the "*process of extension*," while dilatation of the os and cervix occupy such a considerable time, comparatively speaking, even with the additional help of *Nature's hydrostatic dilator*, viz.: the bag of waters?

The drawing back of the perineum produces no additional suffering, as it is done during a uterine contraction. However, when the head begins to bulge the perineum, and its distension is such as to indicate peril to its attenuated structures, I order the patient placed in the left lateral (English) position obliquely across the bed, with the nates brought to its verge, the thighs and legs semiflexed, and the right thigh supported during the period of contractions, by the hand of the nurse, is held in a position raised about 18 inches from its fellow.

Placing my hands, with thumbs parallel, upon the perineum, about 1 inch from its median line on each side, the tips forward and on a level with

<sup>77</sup> Hodge's System of Obstetrics, p. 422.

the posterior commissure, the fingers grasping the tissues around the nates on each side respectively (See Fig. 1), I am able to give the greatest possi-

FIGURE 1.—Illustrates the application of the hands, with thumbs parallel upon the perineum, about one inch from its median line on each side, the tips forward and on a level with the posterior commissure, the fingers grasping the tissues around the nates on each side respectively. Thus the greatest possible aid can be given by exerting pressure during the efforts at expulsion by the uterine contractions, in such amount, in such direction, and at such parts of the thumbs and palms, as the necessity of the case may demand.

ble aid, by exerting pressure during the efforts at expulsion by the uterine contractions in such amount, in such direction and at such part of my thumbs and palms as the necessities of the case may demand. (See Fig. 2.) This is a combina-

FIGURE 2.—Illustrates the natural bulging of the perineum, by the child's head, in the various stages of extension and flexion, in its advance during exit from the parturient canal. This also shows the convexity of the perineum, and the even application of the hands (compare Fig. 1), whereby the pressure is so evenly distributed as to avoid that perilous excitation of expulsive efforts, through reflex stimulation, that is caused by the localized, partial and unequal pressure (a fact elicited by W. Tyler Smith<sup>4</sup>), when but one hand or the fingers are employed. Here can also be seen how pressure exerted at different parts of the palm, or thumb, or both combined, in different directions, will aid in sustaining extension or flexion of the head, and in bringing to aid the tissues from the adjacent parts, and by pushing forward and upward, secure the natural advance of the fourchette, as well as the right angle of the plane of the vulvar outlet to the axis of exit of the parturient canal.

tion method—support with a view to relaxation. Pressure can be so exerted at the palms in the direction of the axis of the inferior strait, with a view of extension of the head, and later on in a more forward direction with a view of sustaining flexion of the head; at the tips of the thumbs with a view of retarding the head and preventing its too sudden exit, and also to aid in sustaining flexion of the head during its exit: while pressure at the same time upon the pelvic floor, so exerted as to endeavor to bring the thumbs closer together with a view of pushing the skin from adjacent parts toward the fourchette, thereby securing the greatest possible diameter of the vulvar outlet in that its plane is brought nearest at right angles to the axis of exit of the parturient canal—(as pointed out by Garrigues—See Fig. 3), as well as furnish-

FIGURE 3.—(After Barnes).—This illustrates several facts rarely referred to in text-books.

The distance from A to F—the anus to the fourchette—is greater than the distance from B to A—the coccyx to the anus—while in the non-parturient state the latter is only about one-half that of the former; thus showing the elongation of the perineum during the exit of the child's head. This elongation of the perineum, and the bending backward of the coccyx, contribute to the hemispherical contour of the perineum noticed in parturition. (Compare Figs. 1 and 2.)

Here we have illustrated also the fact as pointed out by Garrigues,<sup>†</sup> "in order to get the greatest diameter of the vulvar outlet, it should be as nearly as possible at right angles to the axis of exit to the parturient canal." And again, the natural fact of this downward and forward movement of the posterior perineum, as elicited by Goodell,<sup>‡</sup> "the fourchette approximating the level of the symphysis," which must be aimed at in endeavoring to render aid successfully.

ing the greatest amount of skin for its dilatation, and preventing rupture. It must be remembered that the perineum admits of a division into two parts, viz.: the *vulvar or external*, and the *vaginal or internal*; the former lies external to the muscles and the latter includes all the rest. Indeed, much has been written lately of the structure of the perineum, and it is interesting and profitable to carefully note the discoveries as made by the recent investigations of Ranny,<sup>73</sup> D. Berry Hart,<sup>74</sup> Savage,<sup>80</sup> Thomas,<sup>81</sup> and Garrigues,<sup>82</sup> which not only tend to overthrow the prevailing views concerning the muscles and other structures of the

<sup>82</sup> Obst. Treat. of Perineum, in Am. Journal of Obstetrics.

perineum, but more especially to the latter two are due the facts of pointing out the imperfections of the descriptions of this part of the body in the various works on anatomy. The latter in particular seeks to correct many current false impressions. He says: "The fourchette, so generally torn in first labors, is not a fold of mucous membrane, as usually supposed, but is formed of skin. It is, indeed, nothing else than the posterior junction of the labia majora; just within is the *fossa navicularis*." The elaborate description of the floor of the pelvis is well worthy of study, but is too lengthy to be reproduced in this paper. Emmet<sup>3</sup> more aptly than any other, illustrated the muscular lesion in laceration, when he compared it to the drawing aside of curtains, as evidenced by the anatomical relations of the muscles, from the above named investigations. My object in calling the attention of the Association to these facts, is to secure cognizance of all the essentials necessary to obtain the best results.

Finally, my personal experience of no less than from twelve to fourteen years with the "manner of management" proposed and advocated in this paper, warrants me in confidently commending it. But, to succeed with it, requires a most thorough comprehension of the principles upon which it acts, and most faithful painstaking in every detail of its execution.

As the country general practitioner and the eminent city accoucheur likewise, may unexpectedly meet with parturient wounds of the perineum, even when the utmost caution and care have been exercised by following the plans and advice of well known and leading authorities, we deem it not out of place to have a free interchange of experience and opinion respecting the best means to preserve the perineum intact.

I feel warranted in saying, that any physician who does not earnestly labor to acquaint himself with the farthest advancements, and zealously endeavor to observe well established laws which are life-saving and health-giving, in the discharge of the duties of his calling, perpetrates the greatest wrong on his patient. It will not avail to abuse or ridicule the specialist. Those unsealed lips will speak out in future against the man who does not heed the warning. How much better, then, to prove ourselves like the clerk of Oxenford in Chaucer:

"Gladly wolde he lerne, and gladly teche."

#### REPORT OF CASES.

I beg leave to narrate several cases in practice, demonstrating the principles advocated in this paper. But, let me not neglect the all-important fact, viz.: Should rupture occur, the IMMEDIATE operation for repair must be resorted to. The fallacy and danger of delay in the work of repair cannot be too clearly pointed out, nor too

positively condemned. Of the different steps of the operation I shall not speak, but earnestly advocate that the clear and rational teachings of Emmet, Goodell, and others, be definitely and absolutely observed in detail, and success, in all reasonable measure, must result.

#### HOT WATER.

*Case 1.*—At 7 o'clock A.M. on July 28, 1878, I was called in consultation with Dr. Bechtle, to a case of placenta prævia. Hastening to the place, I found the patient had been in labor and flowing all night, and had lost a considerable quantity of blood; the labor pains from the outset were strong and frequent; that she was of lymphatic temperament, anæmic, nervous, and very irritable, of a tuberculous family and 26 years of age, and in labor with her first child. An examination revealed a very rigid state of the perineum and soft parts, the touch of the finger to the vaginal walls producing a spasm of the tissues almost similar to vaginismus, thus it was with difficulty that I inserted my finger sufficiently high up to reach the os uteri, which was dilated to about the size of a silver quarter-dollar, its edges thin, wiry and unyielding, while the diagnosis was confirmed.

Blood-letting being here contraindicated, chloroform inhalations were considered and advised as the best means to overcome the difficulty, but the patient absolutely refusing to take the same, we were thrown upon our resources for something to aid us and relieve, at least in part, the difficulty and suffering. Nauseating doses of emetics were duly considered, but discarded, whereupon I suggested the use of *hot water*, which being consented to, a rectal enema of 1 quart of hot water, of about 120° F., was administered with patient in the left lateral semi-prone position, during the interval of pains, while *hot water* (as hot as the patient could suffer comfortably), wrung out in clean cloths, was applied over the perineum and vulva (after being first well lubricated with warm lard), with my hand underneath, so as to notice with finger in vagina, the effects upon the tissues. The patient soon became more quiet, the parts began to assume a disposition to relax very perceptibly, and in less than five minutes the os uteri was dilated during the first contraction following, so that immediately thereafter I could readily pass my hand into the uterus; version being accomplished and the child delivered through a well relaxed vagina, perineum, etc.

*Case 4.*—Mrs. M. S., æt. 37, German, well developed, muscular and plethoric, composed but irritable, married one year, was taken in labor with her first child at about 7 o'clock P.M., June 14, 1889; the pains being mild at first, but continued increasing in frequency and severity till 10 o'clock, when they "came on" regularly every three to five minutes. It was probably an hour later before the patient would consent to an ex-

<sup>3</sup>Trans. Am. Gyn. Soc., 1883.

amination, which being then made, revealed a *very rigid* perineum and soft parts, the os uteri dilated to about the size of a silver half-dollar, with edges thin, wiry and unyielding, the uterine contractions frequent and very powerful, causing her great suffering, the child presenting vertex anteriorly, right; foetal heart sounds distinct. I immediately concluded the better course, and advised blood-letting as a means of giving speedy relief and an easy delivery. The patient not only seriously objecting to this, but to anything whatever to be done to her person, saying most emphatically: "I want to be left alone entirely," consequently no attempts to give aid were made until about 7 o'clock A.M. June 15, when she began to give evidence of exhaustion from the long continued powerful contractions, which continued with the same regularity and severity all night, but now they began to grow weaker and less frequent, and at her request I made a second examination, which revealed a completely dilated os uteri, the head during the contractions bulging the perineum, which was, however, still rigid and unyielding, the foetal heart sounds were likewise less distinct. Bleeding was again proposed but likewise rejected by her. I then suggested a hot water enema, which was consented to, and at once placed (using over 1 quart of hot water, 120° F.), which she retained without difficulty for about half an hour, the uterine contractions increasing in tone for several contractions, but as soon as the water was voided commenced to weaken down again. I now made an examination for the third time, and found the perineum comparatively soft and disposed to dilate. Hot water, 130° F., was applied (wrung out in clean cloths) to the perineum for about twenty minutes, when I noticed a discharge from the vagina of a dark red and greenish hue. Suspecting the danger to the child, I listened for its heart sounds, and failing to hear them, I kindly informed the patient of the fact, urging the use of the forceps, to which I soon received her consent. It was now about 8:15 o'clock A.M. June 15. I immediately applied the forceps, and in about ten minutes more had delivered the child through a perfectly relaxed perineum. The child, however, was cyanosed, drew several breaths and expired. The placenta was born with the child. Here we have a clear case that, had blood-letting been consented to early, when first proposed, the child would have been saved as well as the perineum. It also proves that hot water alone is sufficient to produce relaxation of the perineum.

The death of the child being evidently due to the abnormal rigid state of the perineum, and the powerful continued uterine contractions causing a too early separation of the placenta from the uterine walls, the uterine contractions becoming too weak from exhaustion to expel the foetus, even though the perineum became relaxed.

## BLOOD-LETTING.

*Case 2.*—In May, 1875; I<sup>4</sup> was requested by my preceptor to visit a woman who had been in labor nearly two days. On arriving at the patient's house, the midwife in attendance gave me the following account: The woman, she said, was large and fat, in labor with her first child, and 33 years of age; that she had been in labor forty-six hours, at the commencement of which everything appeared to do well; that the labor, though slow, gradually progressed until the head of the child had passed the mouth of the womb, after which, notwithstanding the pains were strong and frequent, no further progress was made. On making an examination, I found the head firmly wedged in the vagina, the external parts very firm and rigid, and it was with difficulty I could introduce two fingers into the os externum.

Here it was evident, that the rigidity of the external parts was the sole cause that retarded the birth of the child. I therefore immediately determined to bleed my patient, in order to effect a relaxation of the parts. My intention was to bleed *ad deliquium animi*; but after drawing off 48 ozs. of blood and finding there was no tendency to syncope, I stopped the bleeding to examine the state of the parts. I now found that they were very much relaxed, and that the head was slowly advancing, yet so perfectly easy was the patient, that it could not be ascertained from external appearances that the uterus was contracting. I then requested the midwife to take the seat, that I might tie up the arm, and before this was effected my patient was delivered of a large, healthy child, and declared that she did not experience the least degree of pain during the expulsion.

*Case 5.*—Mrs. J. K., æt. 46 years, the wife of a well-to-do Pennsylvania farmer, a large, muscular and well developed woman, sanguine temperament—being very plethoric; the mother of fourteen children, having had a comparatively easy labor with all, her children always being small at birth. Became in labor with her fifteenth child on the morning of the 13th day of March, 1885. During that entire day and night her pains were very frequent and strong, yet had so little effect in dilating the os uteri, that on the morning of the 14th it was only opened sufficiently to ascertain that the vertex presented anteriorly to the right. She continued suffering considerably from the violent contractions of the uterus, till 2 o'clock P.M.; but notwithstanding this strong action, the perineum remained inflexibly hard and tense, though the os uteri was fully dilated at 10 A.M. In the meantime I tried hot water enema, but it was impossible for her to retain it, while the injections of lard and hot water fomentations ex-

<sup>4</sup> William B. Dewees' Thesis on Means of Lessening the Sufferings of Parturition, for the Degree of M.D., University of Pennsylvania Medical Department, class 1877, p. 19, case vi.

ternally gave good effect upon the vulvar portion of the perineum, yet the muscular or deeper portion remained unyielding.

She being opposed to bleeding, I resorted to chloroform, which was absolutely ineffectual, making no impression or perceivable effect in relaxing the deep perineum unless pushed to a stage of complete anæsthesia, when the uterine contractions were arrested simultaneously with the relaxation of the perineum, and the moment the anæsthetic effects wore off, the uterus regained its vigor and the muscles of the perineum regained their former rigidity. This being repeated several times with similar results, I now obtained consent to bleed, and she lost by venesection 16 ozs. of blood. This, however, produced no effect; the perineum still retained its pristine rigidity at 4 o'clock P.M., when the uterine contractions began growing weaker from exhaustion. At about 4:30 P.M. I drew off from the vein in her arm 20 ozs. more of blood. So immediate was the relaxation of the perineum and the revivifying of the uterine contractions, that in twenty minutes she was safely delivered of a 13-lb. male child.

It may not be out of place to state that this woman's last previous child was born eight years before, that she had grown much more fleshy and fat, having increased in weight, up to the time of becoming pregnant the last time, 65 lbs.

Here we have a most striking case of the good effects of blood-letting in relaxing the perineum.

#### CHLOROFORM.

*Case 3.*—Mrs. R. W., <sup>85</sup>æt. 32 years, being in an advanced stage of tuberculosis—the diathesis being hereditary, father and mother both having died from consumption—and a very nervous and irritable woman, had always suffered very much and long during all of her previous six confinements. This woman was taken in labor with her seventh child on the morning of June 2, 1876, and continued in great misery until the following day, when I was sent for. At 6 o'clock P.M., when I reached the lying-in chamber, I found her suffering excruciatingly, the pains returning every five minutes, and were violent in their nature. Upon making an examination the os uteri was dilated about the size of a gold dollar, the edges very thin and wiry, the perineum very hard, and the rectum filled with scybala. A warm water clyster unloaded the rectum, warm lard was freely applied to the perineum and vulva, and chloroform inhalations followed.

The patient was almost immediately relieved from the extreme suffering, while the uterine contractions seemed to come on more gradually and continue longer, and more powerful. There was none of that excited character in the contractions which distinguished those prior to the inhalations. The patient was not allowed to become insensible

from the chloroform. Immediately after each subsidence of the contractions the chloroform was withdrawn—the interval of repose between the contractions becoming longer and more restful—and immediately upon their return was it again placed to the nostrils as before. This was continued during the entire delivery. After a few contractions had taken place after the chloroform inhalations were begun, I made an examination and, to my surprise, the os uteri was fully dilated, the bag of waters bulging the perineum, and the soft parts were fully disposed to dilate. I now ordered the midwife to place the chloroform, immediately after the return of the next contractions, which I would announce to her. This being done, I carefully watched the effects of the contractions, which were powerful, as they broke the waters and expelled the child, in this one permanent contraction; the patient declaring herself to have experienced almost no pain. The time occupied in the full dilatation of the os uteri, perineum and adjacent soft parts, and the delivery of the child, from the first inhalation of the chloroform, was about forty minutes. There were no evil after effects to either the child or the mother.

*Case 6.*—Mrs. J. O., æt. 20, American (born in New York); medium height, well developed, of lymphatic temperament, nervous and irritable. Menstruated last the first week in October, 1888, hence by regular calculation would have been due July 8 to 13, 1889. *Primipara.* After suffering from irregular periodic pains for several days and nights, I was called on the morning of June 24, 1889. An examination revealed a normal os uteri, with no disposition to dilate, nor was any decided contraction of the uterus manifested during the period of pains. All considered, I concluded to trust the case to nature for further developments. At 8 o'clock on the same day, evening, I visited my patient again and found her in a similar condition. Satisfied that the suffering was caused by spurious, premature or "false pains," I accordingly administered a  $\frac{1}{2}$  gr. dose of morphine, which produced a quietus, and she had a refreshing sleep and good rest all night, as she informed me on my visit the following day. She was free from pain until the evening of the 25th of June, but concluded to pass the night without any attempt to get relief, and thus she continued in more or less suffering from irregular periodic pains until about noon of June 28, when she perceived a decided change in the character of the pain, which now became more regular and cutting. The midwife in attendance, noticing "a show" about 2 o'clock P.M. on the same day, dispatched the husband for me. Upon my arrival I found the patient in labor, contractions regular and forcible, about every five minutes, the os uteri dilated to about the size of a double eagle, and yielding naturally at each contraction. The perineum, however, was very rigid and promised some

<sup>85</sup> Loc. cit.—Author's Thesis, p. 22, case x.

difficulty ahead. Everything progressed naturally till the os uteri was fully dilated, and the bag of waters bulging the perineum, which proved unyielding; the liquor amnii being discharged naturally at about 4 o'clock, when the head advanced upon the perineum at each contraction, but in vain. I now tried hot water enemata, but she was absolutely unable to retain them. I then applied freely and continuously hot water fomentations and innuitions of lard to the perineum and vulva, and though its effect upon the vulvar portion of the perineum was very perceptible, yet it did not overcome the irritable contractions of the muscular or deeper portion of the perineum. I labored thus with the case patiently and hopefully until 8 P.M., when the uterine contractions began growing decidedly weaker from exhaustion, so much so that the case presented a dangerous outlook. Consequently, after securing the consent of both patient and husband, I dispatched a messenger to Dr. F. B. Browne, who arrived promptly, and administered the chloroform, to a stage of semi-anæsthesia only (the patient declaring afterwards that she was conscious of all that transpired, but that she suffered very little pain), while I applied the forceps and by 9:15 o'clock had delivered a healthy boy of 8 lbs. through a perfectly relaxed perineum, the muscular contractions of the perineum yielding immediately under the chloroform, while the uterine contractions increased, and the head "turned out" with the forceps, leaving the tissues of the perineum all intact.

Here, then, we have a clear demonstration of the effects of chloroform in relaxing the perineum.

## THE CLINIC.

### REPORT OF CLINICS ON DISEASES OF CHILDREN.

BY WILLIAM B. ATKINSON, A.M., M.D.

OF PHILADELPHIA, PA.

[Reported for THE JOURNAL.]

#### CHOREA.

*Gentlemen:* This little patient presents a form of trouble which you are sure to meet with constantly when you engage in general practice. Her age is seven years. You will observe that she has a vague manner of moving her hands—an aimless motion, occasionally a twitching, and which she is wholly unable to control. This is commonly known as St. Vitus' Dance, Chorea Sancti Viti. The case before us is not an aggravated one, and evidently is yielding to the remedies which have been employed. This affection occurs almost entirely during the earlier years of childhood, but may be seen in older children, especially at puberty. While it does occur during

infancy, this is extremely rare, though cases are recorded as young as a few months. Its *causes* are in the majority of instances anæmia, rheumatism, fright, imitation, the presence of intestinal parasites, more rarely of indigestible substances in the alimentary canal, or the excitement incident to uterine awakening, as at the approach of the menstrual discharge.

In my experience, anæmia and rheumatism have been the prodromes of the affection in the large number of cases.

Females are the sufferers in the proportion of two to one male. This may readily be accounted for when we reflect that they are less muscular, more endowed with nerve power. Among girls brought up in the open air, permitted to run and jump, and partake of the exercises which I am glad to say are rapidly becoming fashionable for the girls, here we rarely, I may say never, see this disease. But when a girl is confined for hours to her tasks, in a close poorly ventilated school room, under a harsh teacher, who regards asperity, not gentleness, as the proper method by which to enforce her commands, need we wonder that the child becomes a weak nervous being, or that she soon develops the symptoms of what is known as "nervousness?"

The symptoms are easily understood and the nature of the case recognized. There is an alternate contraction and relaxation of the muscles, generally of the hands, the face, the feet, sometimes of the whole body. The latter form is very rare, and may be taken for a convulsive attack. This is general chorea, and is much more rarely seen than the partial form. In the latter, there may be a constant movement of the hands and feet of one or both sides, or merely the almost ceaseless contraction and relaxation of the facial muscles, particularly of the eyes and mouth. The muscles of the left side are those most likely to be affected, as we see in the case before us. Undoubtedly this is due to the fact that the nerves and muscles of the left side are in the great number of persons less under the power of the will.

Let me in this connection urge you to consider the good results incident to the equal cultivation of the muscles of the left as with the right side. Every child should be encouraged to use its left hand as well as the right. Yet we are such helpless imitators, such creatures of fashion, that when a child in its earlier years attempts to use the left hand we at once resort to all kinds of plans, even cruelty, to break it of the so-called bad habit. Every child should be ambidextrous.

Except in rare instances, as where the cause is fright, the approach of the affection is so gradual that it is not observed, or disregarded as a careless trick of the child. With more or less rapidity the irregular movements become more pronounced; the grotesque actions of the child at-

tract attention, and often it becomes an object of ridicule. This acts to fan the flame, and in its annoyance and efforts to avoid observation, the sufferer is rendered rapidly worse. Except when asleep the affected parts are in constant motion, the actions are awkward, the hands are put forward to take an object and aimlessly withdrawn, the child spills its food on the way to the lips, the talking becomes a task in consequence of stuttering, and in aggravated cases the gait is irregular, although some writers deny that this ever occurs. Occasionally we find this affection associated with incontinence of urine. Upon inquiry this proves true here. This complication is of such importance and of so frequent occurrence that I shall have abundant opportunity to discuss it at these clinics. Again, in many cases we find it associated with "night terrors." Of this also we shall make a separate lecture.

The diagnosis rarely becomes difficult. Unfortunately, it too often is not recognized sufficiently early, and is regarded as the result of a bad habit or thoughtlessness, and treated accordingly by harshness or punishment, which adds to the original trouble. A child that is at all nervous is constantly in dread lest it may do something to incur additional fault-finding.

What prognosis can we give in such cases? From my own experience—which has been quite a large one—I may assure you that sooner or later these cases are sure to recover. Although I have encountered a number of very grave cases, yet I never knew one to end fatally, or to terminate other than in complete recovery. In one case which followed a very severe attack of rheumatism in a weak miserable little boy, the attack assumed for a short time the appearance of eclampsia, and the clergyman was summoned to prepare him for death. However, after a tedious attendance he entirely recovered. While as a general rule these cases rapidly recover, yet occasionally relapses occur and the patient appears as though making no progress. In the majority of cases upon investigation I have been able to prove these aggravations to have been due to natural causes, and might have been prevented.

You are no doubt anxious to learn what treatment promises the best results in such an affection. In this instance the child has been using the solution of the arsenite of potassa, in three drop doses three times a day, and is rapidly improving. In the employment of any of these toxicant remedies, I believe that the secret is to continue and push the remedy until its effect is shown by its special toxicant effects.

I would not have you regard any one form of medicament as the treatment for chorea. In all diseases of children my rule is to act according to indications. Never treat a disease by name. This is the most arrant empiricism. Always treat indications. Learn if possible what is the

cause of the attack, and remove or obviate it if you can.

When anæmia is present give some form of iron and combine it with bark. The ferrated elixir of cinchona is a remedy which children can easily take, and rarely fails of being beneficial. The compound syrup of the hypophosphites also acts well. Build up the system with tonics, proper diet, air and sunshine. In mild cases we need nothing more. Of course, take the child from its studies, and if exposed to influences likely to act badly, remove it to a more congenial situation.

In very many cases we must administer arsenic in some form. The usual preparation employed is what is known as Fowler's solution. Let the dose be small at first, repeated every three or four hours, and continued until its effect is shown by improvement, or by a puffiness beneath the eyes, slight nausea, etc. Then keep up the effect, either until the symptoms of the affection are entirely gone, or if these do not yield, or the toxic effects become too pronounced, it is time to resort to some other form of therapeutic. In the same way strychnia is employed, and several authorities prefer it to the arsenic. All agree that it should be exhibited in extremely small doses at the outset, and gradually increased till the peculiar effects of the drug are shown. These are slight cramps of the muscles, particularly of the calf of the leg. Both with this and the previous remedy I caution you to watch carefully the results, as in both I have occasionally seen the toxic effect suddenly produced. While I feel confident that you will generally cure your patients by the treatment indicated, yet it is necessary to say that now and then you will encounter a case which seems to defy your efforts. Here you may resort to the oxide, sulphate, or preferably the valerianate of zinc. The latter, combined with the valerianates of iron and quinine, will often give speedily the best results. The objection to this is the pill form in which it must be administered in many cases.

Should the movements become excessive so as to tire the child or threaten convulsions, the best thing is the use of the bromide of sodium, which may advantageously be combined with chloral. Do not forget why I prefer the sodium to the potassium salt. The former acts as readily, and without interfering with the digestion or the kidneys.

A variety of other methods of treatment have been proposed and employed, as electricity, serpentaria, etc., but they do not offer any better results. In the very large number of these cases seen here in the past, and which you will see constantly at my clinics, it is extremely improbable if one has occurred or will occur that will not readily succumb to the good effects of tonics, arsenic, strychnia, good diet and sunshine.

## MEDICAL PROGRESS.

**THE REPAIR OF OSSEOUS DEFECTS AFTER TREPHINING.**—DR. R. JAKSCH (*Wiener Med. Woch.*, No. 38) reports a case in which he repaired a loss of substance in the skull after the removal of a depressed piece of bone  $3\frac{1}{2}$  cm. in diameter. The operation consisted in the transplantation of bone taken from the head of a gosling a few days old, and was performed ten days after the operation of trephining. At this time the wound was granulating nicely. The down was removed from the head of the gosling, the head itself was then cut off and received in a vessel containing a 2 per cent. solution of carbolic acid warmed to the temperature of  $38^{\circ}$ – $40^{\circ}$ . The top of the skull was then removed under water by means of a forceps and scissors. It was then divided into eight small plates, which were laid in proper order directly upon the granulating dura mater of the patient. An antiseptic bandage was next applied. This was allowed to remain for ten days, and upon its removal all the little bone plates were observed to have a rosy color and to adhere fast to the underlying tissues, while their points of separation were indicated merely by fine lines. Eight days later little knobs of granulation were seen upon the bone plates, while the former lines of separation had disappeared. Upon gentle pressure a parchment crackling was elicited. One week later the whole surface was granulating and no parchment crackling could be obtained by pressure. From this time on granulation advanced rapidly, and fifty-five days after the operation bony union was complete. At the point of injury there was nothing to be seen but a scar and a slight depression. The operator purposely left the wound open, in order that he might observe the progress of repair, and is convinced that vitality was preserved in the bone plates, and that the ossification of the opening in the skull proceeded from them. The transplanted bone plates effected an organic connection with the surrounding parts.

The writer gives the following brief summary of bone transplantations in such cases:

1. Reimplantation of the pieces of bone removed by trephining (MacEwen, Adam Kiewicz, Guérin).
2. Transplantation of pieces of bone taken from another bone of the same individual (Leydel).
3. Transplantation from one animal to another of its kind (Adam Kiewicz, Guérin).
4. Transplantation from one animal to another of a different genus (Guérin).
5. Transplantation from an animal of different order (author's case).

**A NEW METHOD OF DELIVERY IN BREECH PRESENTATION.**—DR. MARS (*Med. Uebersicht*) de-

scribes a method of extraction in breech presentation which he has successfully employed three times during the last twelve years. In the first position of the breech he introduces the right hand between the back of the child and the walls of the uterus, while the left hand is employed to control the uterus. The second, third and fourth fingers of the right hand rest upon the child's back, while the thumb and little finger seize the body by the crests of the ilium. During labor pains the accoucheur draws down until the present part appears at the pelvic outlet, when extraction is completed in the usual manner.

**TREATMENT OF PYOSALPINX.**—GOTTSCHALK reports (*Centbl. für Gyn.*) his experience with Walton's method of treating pyosalpinx by uterine drainage, preceded by dilatation. He regards the cases of simple collections of pus enclosed by thick walls in normally developed tubes as the only ones suited to such treatment, while the long sausage-shaped tumors with thin walls, separated from each other by indentations such as form in infantile tubes, should only be dealt with by extirpation.

A complete dilatation of the uterine canal prevents retraction of the walls, and in this way a *vis a tergo* is established, permitting the escape of the purulent contents of the tumor. Walton claimed to remove the obstacles to the escape of pus by means of the curette, but the reporter believes it quite improbable that one can directly dilate the tubal orifices by the sound or curette. Gottschalk's plan is as follows: Strips of iodoform gauze are carefully introduced into the uterus and removed the next day, when the uterus is washed out. Gauze is then again introduced in such a manner as to fill up the cornua as much as possible. This is repeated daily several times, and finally the tampon is allowed to remain for three days, until the uterine cavity becomes so much distended that all parts of it can be explored by the finger. Pains like those of labor are excited in this manner. In his two cases so treated the pus cavities were emptied and the patients recovered. When the pus begins to flow the uterine cavity is kept loosely packed with gauze, into which the pus escapes, and the irrigations are continued. If such a plan as has been described is not successful, the curette may be used, although the reporter avoids its use, as it may cause the pus sac to burst.

**CODEINE IN DIABETES.**—B. NOVARO (*Gaz. Med. di Torino*), has employed codeine successfully in cases of diabetes which have resisted other treatment. He prescribes 1 grain of codeine divided into 20 pills. Three pills are given the first day, and if well borne the dose is increased by 1 pill each day.

SATURDAY, DECEMBER 14, 1889.

THE CONTAGIOUSNESS OF TUBERCULOSIS.

Not least among the advances of the century is the establishment of the fact that phthisis may be transmitted. The labors of LISTER taught the value of cleanliness even to those surgeons who do not accept all of his conclusions, and the investigations of KOCH have done a like service to the general practitioner. There are many who are yet unable to decide whether the bacillus tuberculosis is the cause or the result of phthisis; indeed, the feeble response that is made to the most approved methods of administration of the most available germicides, suggests very forcibly the thought that other factors may be equally necessary to the causation of consumption, and that the bacillus is not alone all powerful for evil.

However this may be, one thing seems to have been clearly demonstrated regarding the etiology of phthisis, and that is, that the disease is transmissible; that it can be carried from one who is the victim of tuberculosis to another who is free from it. If the bacillus is not the main cause of phthisis, the conditions which favor the growth and multiplication of the parasite are those which favor the development and progress of tuberculosis.

The testimony of experimenters and clinical observers is now almost conclusive as to the possibility of the transmission of tuberculosis, although there is yet and probably always will be, a difference of opinion held as to the manner of dissemination and the way of entrance. M.

VILLEMIN, on behalf of a permanent committee appointed by the last Congress for the study of tuberculosis, to present practical conclusions concerning the prophylaxis of tuberculosis, has affirmed that tuberculosis is a virulent, contagious disease produced by a microbe (Koch's bacillus), which apart from hereditary transmission, finds its way into the organism through the respiratory and digestive tracts, and through wounds of the skin and mucous membrane.

There is probably not much importance to be attached to the idea of the hereditary transmission of the bacillus; in fact, is not the value of heredity as a cause of phthisis rapidly diminishing as the doctrine of contagion is made more lucid? A few years ago the victim of tuberculosis from a family in which there had been other cases, was generally thought to have in some way inherited the disease; to-day we ask if it is not probable that in consequence of close association with one or more of these cases, he acquired the disease by direct transmission of the cause.

It is well not to entirely dismiss the subject of heredity as having no part in the causation of phthisis. While direct inheritance of the disease is not probable, yet certain conditions of physique and temperament may be inherited, that favor the rapid development of the determining agent whenever it is implanted. Though it is possible that tuberculosis may be developed in a person previously in good health, yet we must conceive that it is more easily transmitted to one who through inherited or acquired systemic fault, has diminished power of resistance to disease.

Believing then that tubercular products may be carried to and planted in tissues that are ready to receive and nourish them, the study of prevention is at once suggested. So far, only partial success has crowned the efforts to eliminate the disease after it has once become established. Hence, the most important question of to-day is, can phthisis be prevented? Can the germs of tuberculosis be so thoroughly destroyed that the unaffected shall not be in continued danger from the disease?

In nearly all cases it is thought that transmission occurs in one of two ways: by the inhalation of tuberculous germs, or by their entrance into the alimentary tract with food. The two main sources are, the expectorated material from tuberculous subjects, and meat and

milk from tuberculous animals. It is distinctly asserted by careful investigators that the tubercle bacillus can live in the dried muco-pus, which in the form of finely reduced dust, can enter either the respiratory or alimentary tract. Here the physicians duty is plain.

The sputa of a tuberculous patient can easily be prevented from becoming dry and disseminated through the air, especially if the patient be unable to leave his room or house. Cuspidores should contain a solution of bichloride of mercury not weaker than 1-1,000, or what is probably quite as efficient, a strong solution of concentrated lye of the groceries. The cuspidores should have straight sides so that the sputa may not dry on its surfaces, and all clothes used for receiving expectoration should be kept moist and finally burned. If even this much were insisted upon both in the sick room and about hotels and health resorts, it would surely limit one great source of transmission.

The physician should go farther than this, and insist that no one be permitted to share the bed of a consumptive, nor to sleep in a bed or occupy a room that has been used by a victim of advanced phthisis until the best known methods of disinfection have been thoroughly carried out.

Prevention of transmission of tuberculosis by diseased food is a more difficult matter, yet much may be done by a careful medical attendant to lessen the danger. A consumptive mother should not nurse her child to the possible injury of both. If cow's milk be substituted, care should be taken that the source of the supply be healthy. We may not be able to estimate, but we can often prevent the danger that threatens children, especially in the city, who are daily absorbing milk from swill-fed and often diseased cows. It is no wonder that intestinal diseases closely allied to tuberculosis are constantly found in little children when the substitute for the mother so far as food is concerned, is a feverish cow, closely confined in a dirty shed and fed upon fermenting kitchen refuse and impure water.

Sometime we may have authorized a system of careful inspection of meat, but until then, this duty also must be performed by the physician so far as is possible. It is probable that diseased meat is a much less potent agent in the dissemination of tuberculosis, than either milk from infected sources or the exhalations and secretions

from phthical patients, yet whatever danger there may be from this cause should be averted.

If the march of so universal and destructive a foe to life can be thus easily limited, no intelligent physician can afford to fail to use his best efforts to accomplish so desirable an end. It is true that there is much more to be done, but this at least is practical, inexpensive and in the right direction.

---

#### DISINFECTION.

The time perhaps is not far distant when a physician's success will depend largely upon his ability to avoid or avert disease, and not to cure it. Our aim at present, in this direction, is mainly in the way of rendering the excreta of the patient, both solid and aerial, innocuous. Theoretically this can be accomplished in one of several ways; practically none of these ways are perfectly satisfactory. In very many cases—in fact in the bulk of cases—it is impossible to absolutely isolate the patient, and more especially the nurse and attendants. Of what avail is it to fumigate patient and room never so carefully, when all through the course of the disease the nurse has carried about and disseminated through the household the contagium of the disease? Again, is it probable that even hours of fumigating an apartment can destroy the germs carried into its crevices?

In considering the agents to be used for disinfecting, not only must we have in mind their efficiency, cheapness and convenience of use, but also their destructiveness. Sulphur burned in an apartment will destroy the coloring to a large extent, and, to be efficient, must be strong enough to do so. Carbolic acid, the chlorine compounds, corrosive sublimate and permanganates act, in the main, locally by destroying the virus held in dejecta and vestimenta, and vary in their destructiveness.

It is becoming a well recognized fact that surgical operations can be performed and healing go on free from sepsis by rendering the operation and subsequent treatment aseptic, and that anti-sepsis is not needed when the wound is aseptic. A somewhat similar state of affairs is probably true in the management of contagious diseases. While attention should be given to the final disinfection of the apartment, much more attention

should be given to the disinfecting of the patient, his surroundings and attendants during the course of the disease than is usually thought necessary, and it is reasonable to suppose that, other things being equal, recovering will take place the better, the more thoroughly this is carried out. With this end in view it should be the daily duty of the nurse to wipe up with a disinfecting solution the dust which accumulates in the apartment. As soon as the contagiousness of the malady is recognized the patient should be isolated and all unnecessary furniture removed from his quarters. Rigid oversight should be exercised with everything used. The matter may be summed up in a few words: Let everything the patient uses be set aside as his only; disinfect after each use of vessels or appliances; use as little furniture and as few utensils as is consistent with comfort.

It is the experience of our German confrères that typhoid fever and pneumonia do well, do best even, in a very low temperature. While some of the good result obtained by them is, undoubtedly, due to the constant change of air, a part is also due to the lowered vitality of the virus from the cold. It may be of service, then, to add to our other disinfecting agents not alone pure air, but cold pure air, and that, too, during the course of the disease.

#### EDITORIAL NOTES.

##### HOME.

THE THERAPEUTIC ANALYST will be enlarged and improved commencing with the January issue.

THE DENTAL COSMOS will commence the 90's by donning a new dress.

THE KALAMAZOO ACADEMY OF MEDICINE will hold their annual meeting during the Christmas holiday week. A committee consisting of Drs. McNair, Van Zwaluwenburg and Hochstein has been appointed to make the necessary arrangements, and some medical gentlemen of National reputation are expected to participate in the exercises. A banquet will be one of the attractions and the election of officers will take place on this occasion. So says the *Physician and Surgeon*.

DR. GEORGE M. STERNBERG, U. S. A., will deliver a lecture before the Brooklyn Institute on the 26th inst. His subject will be "The Methods of Research in Bacteriology," to be illustrated

by living forms of bacterial life thrown upon the screen.

THE JEFFERSON MEDICAL COLLEGE has made a purchase of four pieces of property on Walnut street, in order to make additions to the College and Hospital.

CHRIST'S HOSPITAL AT CINCINNATI.—Additional hospital accommodations are about to be provided under the name of Christ's Hospital. Dr. C. G. Comegys is to be the chief medical adviser and organizer.

POST-GRADUATE CLINICAL COURSES will be shortly commenced at the Johns Hopkins Hospital, Baltimore.

THE ANNUAL REPORT OF THE SURGEON-GENERAL OF THE NAVY.—The annual report of Surgeon-General Browne to the Secretary of the Navy shows that, in addition to the eleven vacancies existing in the Medical Corps in October, 1888, six more occurred during the year—four by death and two by retirement. The transferring of the Medical Examining Board from Philadelphia to New York and the establishment of another Board at Mare Island has been attended with gratifying results, without lowering the standard of proficiency in the examination. A greater number of candidates have presented themselves, and twelve have passed the examination. At present there are eight vacancies in the corps, and there is reason to believe that they will soon be filled.

THE UNIVERSITY PRESS.—The *Philadelphia Inquirer* says that an enterprise in which officers and friends of the University of Pennsylvania have been engaged for some months has just been completed by the establishment of a publishing company under the name of the University Press. A charter has now been drafted and will be applied for. The officers are: Stuart Wood, of R. D. Wood & Co., President; H. La Barre Jayne, Treasurer and Solicitor; A. L. Hummel, M.D., General Manager; and the following Board of Directors: Provost Pepper, Joseph H. Cofrode, J. William White, M.D., Charles C. Harrison, Stuart Wood, H. La Barre Jayne, A. L. Hummel, M.D. (*ex officio*), and G. E. de Schweinitz, Secretary.

The capital stock is \$100,000. Arrangements, however, are being made for doubling this amount,

and it is expected that in the near future the stock will reach \$1,000,000. Among the stockholders, in addition to the officers, are Joseph D. Potts, Thomas Dolan, D. Hayes Agnew, M.D., Samuel Dickson, H. C. Wood, M.D., Edward Martin, M.D., John Marshall, M.D., Dean of the Veterinary Department of the University; James Tyson, M.D., Dean of the Medical Department; John H. Musser, M.D., George I. McKelway, M.D., and Samuel D. Risley, M.D.

The company has been started for the purpose of controlling under one efficient direction the present periodical publications of the University, and of establishing such new magazines as the needs of the institution may suggest.

The addition of six publications to the two now issued under the auspices of departments, the *University Medical Magazine* and the *Political Law Series*, is already assured. The new journals will be the *University Magazine* (literary), the *University Legal Magazine*, the *University Veterinary Magazine*, the *University Biological Magazine*, the *University Psychological Magazine* and the *University Hygienic Magazine*. At least four of these new publications will appear by January 1, when the new organization will begin operations.

DIPHTHERIA seems to be more or less epidemic in all parts of the country.

DR. CHARLES WOLTERS has been elected resident physician to the Philadelphia Hospital, Department for the Insane.

THE NEW YORK BOARD OF HEALTH will take immediate steps to rid the city of the noxious odors arising from the manufacture of gas.

THE MIDDLETON GOLDSMITH LECTURE.—*The Times and Register* says that Prof. Willam Pepper, Provost of the University of Pennsylvania, will deliver the Middleton Goldsmith Lecture before the New York Pathological Society, in the hall of the New York Academy of Medicine, on Wednesday evening, January 15, 1890. The subject of the lecture will be "Hepatic Fever."

THE NEW YORK BABIES' HOSPITAL.—New York claims the honor of having the only Babies' Hospital in the United States. A school for the thorough instruction of nurses in the care of babies will soon be established in connection with the hospital.

## FOREIGN.

PROF. NEUMANN received, it is said, \$20,000 for his professional visit to the late King of Portugal.

PROF. VON KRAFFT-EBING has been appointed successor to the late Prof. Leidesdorf in the Clinic for Mental Diseases in the Vienna Landes-Irrenanstalt.

RICORD is said to have left memoirs of his life and professional career under the suggestive title of *The Nineteenth Century Seen with the Speculum*.

RENAL SURGERY.—Mr. Bennett May writes to the *British Medical Journal*: My attention having been directed to Mr. Lawson Tait's table of operations in the *Journal* of November 16, in which he credits me with being the medical attendant of one of his cases, I write to say that I have no knowledge of the circumstance.

DR. GEORGE N. STEWART, who for more than two years has been senior demonstrator of physiology under Professor Stirling in Owens College, Manchester, has been appointed to a George Henry Lewes studentship. Dr. Stewart's researches, especially on the polarization phenomena in nerves, are well known to physiologists.

DEATH OF A MEDICAL MAN FROM GLANDERS.—The Vienna Correspondent of the *British Medical Journal* writes: A painful sensation has been caused here by the death of Dr. Hofmann von Wellenhof, assistant to Professor Grüber in the Institute of Hygiene. Dr. Hofmann, who was only 26 years of age, had under his care a coachman who had contracted glanders from one of his horses. In preparing microscopic specimens of the bacilli of glanders Dr. Hofmann himself fell a victim to the disease, the infection, as was proved by post-mortem examination, having taken place through the mucous membrane of the respiratory passages. Death ensued very rapidly. It is said that another case of glanders has since come under observation in Professor von Schrötter's clinic.

WHOLESOME FOOD FOR RUSSIAN SOLDIERS.—The medical department of the Russian Ministry of War has decided to establish movable laboratories of toxicological chemistry and bacteriology attached to each army corps. In these laboratories all food supplied to the troops will be analyzed.

## TOPICS OF THE WEEK.

### THE EDUCATION, TRAINING AND QUALIFICATIONS OF THE MEDICAL OFFICERS OF HEALTH.

In the report of a recent meeting in England of the Society of Medical Officers of Health, published in the *British Medical Journal* of November 23d, the President, Henry E. Armstrong, M.R.C.S., commenced his address by observing that the question he had taken for its subject matter had of late attracted much attention, both in and out of the profession. There was a growing feeling "that the medical officer of health should no longer be allowed to learn his profession after his appointment to office, and gain his sanitary knowledge, perhaps after a series of ghastly failures, at the expense of the community by whom he was engaged." Time was when only the ordinary qualifications for medical practice could be required; when in the early dawn of the science of public health "its votaries had to grope their obscure way with feeble and uncertain step;" but those days were now long past. The necessity for an acquaintance with at least the elements of sanitary science by all medical men was already recognized; but how much more was a thorough knowledge of preventive medicine incumbent on those who chose it as their profession? This was now becoming felt even by the public. The idea that "prevention could not be divorced from cure was fast being replaced by the conviction that their union was objectionable on the ground of incompatibility of interests," and he hoped that the appointment to small districts of men engaged in general practice would, before long, be discontinued. The need for special qualifications was beginning to be understood by some sanitary authorities, though it had not been recognized by the Legislature until last year. The first step in this direction was taken in the 18th Section of the Local Government Act of 1888, which enacted that after the year 1891 no person should be appointed medical officer of health to a district or combination of districts having a population of 50,000 unless he possessed a diploma in public health, etc., or had served in that capacity for the three years immediately preceding to one of 20,000 inhabitants, or been for the same time an inspector under the Local Government Board. The Burgh Police and Health (Scotland) Bill went further, demanding the possession of a diploma by all medical officers of health, without exception, and discouraged private practice. Considering the wide range of subjects with which the medical officer must be conversant—legal, statistical and administrative, engineering, chemical, biological, etc.—and the mental training required for the investigation of the problems with which he had to deal, which could not be acquired without prolonged study, Mr. Armstrong was of opinion that not only should higher degrees in public health be instituted, but that aspirants to such degrees, which should rank with the Doctorate in Medicine, might well be exempted from some subjects, as surgery, midwifery, with which they had no concern, and be allowed to offer practical training in sanitary work in lieu of a portion of the clinical practice required of candidates for medical diplomas.

If the departments of curative and preventive medicine should be thus divided, the instruction in the latter given at the medical schools must undergo a great development, and it must be raised into a faculty, instead of being, as at present, looked on as one of the minor subjects. But a grave want in our medical education, from which all students alike suffered, was the absence of all opportunities for the clinical observation of infectious diseases. Many practitioners had never seen a case of typhus, and made their first acquaintance with small-pox and scarlatina after they had entered on private practice, to the injury of their patients and of their own reputation. The records of admission to fever and small-pox hospitals bore witness to the frequent occurrence of errors of diagnosis of the gravest and most dangerous character on the part of private and parochial practitioners. Reviewing the conditions on which the existing diplomas in public health were granted, Mr. Armstrong insisted on the necessity not only for practical instruction in the laboratory, but of a period of service with the medical officer of health to a large town or district. These had, indeed, been recommended by the Medical Council, but had not been as yet introduced into the regulations. This want of administrative experience was painfully felt by medical officers when first called on to report and advise on insanitary dwellings, engineers' plans, or the construction and management of infectious hospitals, and when giving evidence in courts of law. This last requirement might, however, be dispensed with for some time to come in the case of men who had been actually in office for several years. But the medical officer of health, however well prepared to enter on his duties, must keep himself abreast of the progress of his science, and they had a right to claim that those, at least, who were in charge of large or populous districts should be regularly supplied with the reports of the Local Government Board and all like official publications, if only in the interest of the populations for whose well-being they were responsible.

### SUMMER CAMPS FOR FEEBLE POOR CHILDREN.

The following extract is from a paper read at the annual meeting of The American Public Health Association, by DR. JEROME WALKER:

In 1874, Drs. Henry Hartshorne and J. M. Toner proposed summer camps, especially for feeble poor children, as an aid in decreasing the high mortality among young children. It was a question when the proposition was made whether mothers would be willing to leave their husbands and homes, even in the hope of improving the health of their sick or feeble children. In 1875, acting upon the experience of charitable people in Copenhagen, some good people of Boston, started what was known as the "country week," the sending of poor children for a week's outing to farm houses in Massachusetts. Since 1874, cities, societies, churches, newspapers and individuals have instituted "fresh air funds," summer resorts and seaside homes for poor mothers and their feeble children. Very little trouble has been experienced in inducing mothers to go for a week or two with their

children, or to allow children to go by themselves, to the seaside, the country or mountains. The husbands, for the most part, have come to see how much is saved in various ways by these trips, and so great is the rush by applicants that the question now is, how can we reach those who need the change most and how exclude the others? A real danger faces all these efforts to help the masses—the danger of overdoing. The charitably disposed, the philanthropic, the lovers of children, the emotional, people of wealth and leisure struggle to have a large sanitarium, the largest, if possible, and many donors, or trustees or helpers have one or more families in whom they are especially interested, and for whom they are positive the charity was established. Doctors are employed at a small pittance, or are allowed to give their services to show that medical attendance is furnished when necessary, but “change of air” is popularly believed to be all that is needed. The physician is not looked upon as a sanitarian, his highest function, and sanitary matters are relegated to irresponsible people. Large sanitariums become unwieldy and are machines, unable to give the true mother-like care which babies need. Better would it be for the babies if there were more sanitariums and smaller. Properly conducted summer health resorts must help to lessen infant mortality, though it would be hard to prove this statement by figures. A week's freedom from home cares and work, with pure air, an abundance of food, good sea bathing, opportunities to ride, etc., frequently brings the milk into the breasts of women who at their homes had insufficient nourishment and could not nurse their children. Mothers are taught the value of digestible, plain, wholesome foods, of regular times for eating, of cleanliness, to discard feeding bottles with long rubber tubes—“snake” tubes as some one has appropriately called them—to appreciate proper airing of rooms, that bathing not only makes a baby sweeter, but healthier. As I look back over my ten years' experience in connection with a seaside home for children, I can recall to mind woman after woman who has learned to be neat, clean, orderly, sensible, not all in one season, but after several visits to the seaside home. Every woman so trained, must, by the influence of her example, lessen, to a certain extent, infant mortality in the circle of her acquaintances.

Any one who has lived in winter in a light, well-ventilated, but well-warmed tent of generous size, or who has camped out in summer in a well-arranged, comfortable, airy tent, must feel that tent life could be readily and advantageously used for feeble and puny children of our cities. And this tenting need not be at a considerable distance from a city, but upon suitable lots or lands which are to be found within or near to the city limits. It behooves those acquainted with living in properly arranged tents to advocate camp life, and to overcome popular prejudices as to tents, founded sometimes on unpleasant experiences in dilapidated and badly arranged tents at camp meetings and other resorts. Large piers, which project into our rivers and bays, portions of our public parks and anchored vessels in midstream might well be utilized as sleeping places on hot summer nights,

when sleep is the principal factor in the recovery of babies that are ill. How much more good could be accomplished by St. John's Guild if its barge had its inmates on the water for several days instead of for one day! What sanitariums the large iron ocean piers would make! To my mind one of the most important steps toward lessening infant mortality has been made by Dr. Sarah J. McNutt. In the summer of 1888 she fitted up a house in a crowded portion of New York city as a city summer sanitarium. Of the 108 babies received, all sick, 79 were under 1 year of age. Of these 79, 32 died, 22 of the deaths being in July, August and September. Dr. McNutt says: “Although that experience covers as yet only one summer, it seems to us to demonstrate that bottle feeding is not necessarily fatal, even in a hospital, and that a hospital for sick babies need not be a place for the production of autopsies alone.” She shows that the quality of bottle feeding has much to do with infant mortality, and that to obtain the results she did hygienic measures were of paramount importance. The cost of maintenance of each patient in the babies' hospital per week was \$4, a larger amount than most institutions care to acknowledge to the public.

“Line upon line, precept upon precept,” an unflagging and judicious sanitary supervision of our children from their birth until we or they are called hence, will, above all things else, decrease infant mortality to the minimum. On the other hand, injudicious sanitary supervision, the watching of almost every mouthful of food a baby takes, constant anxiety lest the child is going to catch cold, the dread that the blood will be overheated by much exercise, etc., will be likely to worry both parent and child into an untimely grave.

#### MANAGEMENT OF INEBRIATE ASYLUMS.

DR. CROTHERS, of Hartford, Conn., writes as follows:

The first inebriate asylum, at Binghamton, N. Y., was projected in 1844, but was not opened for patients until 1864, twenty years later. This was owing to the intense and bitter opposition to the theory of disease and curability in special asylums.

A good illustration of the historical fact, that every new truth in the progress of the world is greeted with storms of denial and fierce contradiction. This first inebriate asylum was the centre of the most crushing unjust criticism by the press, the clergy and others. Its managers and their theories and methods of treatment were always the subject of condemnation and persecution. The disease of inebriety and its curability in asylums was a great event that could not be suppressed by the change of Binghamton to an insane asylum, and to-day there are over a hundred asylums for inebriates in different parts of the world. Most of these asylums are founded on the fact, now well established, that inebriety is a disease of the brain and nervous system. The use of alcohol in many cases may be only a symptom, in other cases alcohol starts up a train of degeneration which has been inherited, and in all cases there is progressive dissolution of the brain and nervous system, that can easily be reached by medical treatment addressed to the entire

system. The removal of alcohol is only one factor in the treatment, the removal of the causes will always be followed by the cessation of the desire for spirits. All treatment and remedies addressed to one state or condition of the body fail, for the reason that inebriety is not a local desire, and does not come from the use of alcohol alone. Hence the true principle of treatment must include not only restraint, but limited freedom, together with all means known to science to build up and strengthen the entire system. In the largest and best asylums in this country and Europe all cases are treated as sick and diseased, the duration and degree of restraint is modified to meet the demands of each case, and the general treatment aims to remove the special and general causes which have brought on the disease.

It is a deplorable fact that all inebriate asylums are judged by the statements of incurables who have failed to be benefited by treatment. Judged from these criticisms no inebriate asylum could exist long. Those who are more or less cured in these asylums, disappear and never refer to them, or the benefits they have received. The criticisms of our work have been inspired in many cases by the incurables, while those who have been restored have been silent.

## PRACTICAL NOTES.

### EUCALYPTUS IN SCARLET FEVER.

The value of eucalyptus in destroying the infection of scarlet fever cannot be too widely recognized. On October 20 I saw a nurse in a family where there were three young children. She had the rash over her chest and arms, the complaint having commenced about thirty-six hours previous. She was removed to the hospital, and Tucker's eucalyptus disinfectant was ordered to be freely used in the nursery, the children being kept in an atmosphere strongly impregnated with it for three days and nights; after that they were allowed out during the day, but the disinfectant was continued in the nursery for four or five days longer, when they were considered safe.

On October 27th, I saw a girl about 11 years of age, whose sister had been sleeping with her. She had had sore throat for about two days, and the rash was fully out. The sister was not allowed to sleep with her, but she spent most of her time in the room during the next three days, when the new Act came into force, and they were separated. Here the disinfectant was rubbed over the skin of the whole body night and morning for three days, afterwards at night only; the emulsion was administered, and the disinfectant freely sprinkled over the bed and about the room. The girl had a severe attack of fever, had rheumatism in her wrists and ankles for a few days. The desquamation was finished about the fifteenth day, and there was no appearance of albumen in the urine. The sister did not develop

the disease, although exposed to the infection for five days, and three other children in the house did not take it. There was no carbolic or other sheet used over the door, the disinfection of the patient in the way described being sufficient to prevent any of the poison escaping from her.

It is to be hoped that others will try this method of disinfection, as, if it is as effectual in all cases as I have found it in all so treated during the last six months, there is every reason to believe that the infection of scarlet fever may be arrested in every case.—J. Brendon Curgenven, M.R.C.S., *British Med. Journal*.

### MENTHOL IN LARYNGEAL PHTHISIS.

Twenty cases, most of them of a severe type, treated with menthol applications, furnished the author ground for believing that this is a valuable agent in tubercular laryngitis. The drug was dissolved in fluid cosmoline in the proportion of a drachm or a drachm and a half to the ounce, and applied by means of a laryngeal syringe, or in the form of spray, by a nebulizer or vaporizer. In nearly all cases the subjective symptoms and the local appearance improved. In no case did complete healing of an ulcer take place. In this respect the author's experience does not bear out the representations of Rosenberg and others. Three propositions are offered: 1. spontaneous cure of a tubercular ulcer of the larynx may occur; 2. a simple erosion or ulceration may be mistaken for a tubercular ulcer; 3. the best results from local treatment of the larynx may be expected in cases of incipient or limited pulmonary disease, and in primary laryngeal tuberculosis.—Dr. Chas. H. Knight, *Journal of Laryngology*.

### THE USE OF MENTHOL IN THE UPPER AIR PASSAGES.

The drug controls superficial inflammation; that is an analgesic, and second application can be made in increasing strength without discomfort; that it is destructive of some of the low forms of life, especially the bacillus tuberculosis, and that is a valuable antiseptic in nasal surgery. It has an important place in the treatment of atrophic conditions. It can be used in strength of from one to fifty per cent., dissolved in oil. The oleum petrolia the author considers the best for the purpose of dissolving the drug. It can be applied directly by cotton application, or by means of the spray, or by vaporization. The direct method answers best in the pharynx, the spray and vapor for the nose and larynx. Five cases of laryngeal phthisis following upon disease of the lungs were also reported, in which the menthol treatment gave satisfactory results, the local conditions improving rapidly under its use.—Dr. F. H. Potter, *Journal of Laryngology*.

## SOCIETY PROCEEDINGS.

## Medical Society of the District of Columbia.

*Stated Meeting, May 1, 1889.*DR. THOMAS E. MCARDLE, VICE-PRESIDENT,  
IN THE CHAIR.

DR. S. C. BUSEY presented

A SPECIMEN OF GENERAL CANCER, WITH A HISTORY OF THE CASE.

The man was 58 years old. Dr. Busey had attended his family for ten years, but rarely saw him, professionally, as he preferred to consult some physician who would not insist upon his orders being carried out. In 1887 he had attended him for acute desquamative nephritis, from which he entirely recovered. From that time he had no knowledge of him until last January (23d), when he came to his office at night. In November, 1888, while on a visit to New York, he suffered from violent pains in the left lumbar region, which at times extended to the left iliac fossa, and obstinate constipation. For this condition he took drastic cathartics without any relief. After he returned home he was under the care of several different physicians, none of them being members of this society. He continued to suffer from these attacks and constipation, and finally his appetite became bad. The last physician treated him for rheumatism and applied electricity without relief. From the symptoms Dr. Busey concluded that he had some digestive disturbance, and upon a careful physical examination detected a tumor the size of a fist to the left of the navel, which was immovable and could be grasped by the hand. He presented a cancerous cachexia. He kept him under observation for two weeks and then had Dr. Thompson see him in consultation. They reached the conclusion that the tumor was malignant, and agreed to aspirate the following Sunday. Aspiration was performed without result. They then concluded to let him alone for four weeks. At the end of this time the tumor was as large as a child's head, but no fluctuation was detected, although it was thought that it might contain fluid. The question of operation was considered, but neither Dr. T. nor himself would accept it. As the disease progressed the evidences of cancer became more marked and he died April 24th. The pain was mainly confined to the left iliac fossa. The left leg became œdematous, and during the last three weeks of life he suffered from intense dryness of the mouth, which was his most distressing complaint. He never had much pain, and a dose of paregoric at night was all the analgesic required. Constipation was obstinate, but was finally relieved by glycerine suppositories. He died from exhaustion.

Dr. D. S. Lamb made the necroscopy. Body

much emaciated. All the tissues somewhat blanched from the embalming fluid. Firm pleuritic adhesions at apex of each lung; pleura of each lung; especially the upper lobe showed many small, firm, flat, white patches of thickening; multiple fibroma; apex of each lung much contracted and in section showed abundant small, hard, pigmented bodies, possibly obsolete tubercle; these have not been examined microscopically. The pulmonary artery of the lower lobe of the right lung was stuffed throughout with clots, some dark, others pink in color. A few small purulent cavities in upper lobe of right lung. Heart weighed only eight ounces; fatty degeneration of mitral valve; more thickening of aortic valve. Liver weighed fifty ounces; showed many superficial watery cysts and soft masses of cancer the size of a pea to a walnut, some of them intermixed with blood. Spleen small; pancreas normal. There was a large mass in abdomen, left side, below level of umbilicus, composed of coats of intestine united together by soft, granular material, encephaloid cancer, much intermixed with blood and continuous, with firmer portions of some in the subperitoneal tissue over the left brim of the pelvis. This mass was adherent firmly to abdominal wall. The intestinal peritoneum in places showed rounded, soft, pinkish thickenings, also encephaloid cancer. The right supra-renal capsule was normal; the left contained a yellowish, firm, oval cancerous mass the size of a marble. The right kidney normal; the left weighed only two and one-half ounces and showed many small superficial watery cysts, and the pelvis was much dilated from pressure below upon the ureter. Prostate gland enlarged.

A case of general cancer, primary, I think, in the subperitoneal tissue, secondary in the other situations mentioned. The microscopical examination was made by Dr. Wm. Gray, of the Army Medical Museum.

DR. J. FORD THOMPSON: At the first meeting they had agreed that this was not a case for operation. He had recently seen a similar case with Dr. Mauss and had refused to operate. He would not always refuse to operate when the tumor was movable and was confined to a portion of intestine and mesentery which would not necessitate resection. The surgeon determines the conditions and throws out doubtful cases. It requires good judgment to reject cases unsuitable for operation.

DR. J. DUDLEY MORGAN read a paper on

## ACUTE ŒDEMATOUS UVULITIS.

Most authors, in writing of acute œdema uvulæ, or acute uvulitis, affirm or infer that the œdema is caused by or associated with cold, and that the pharynx and tonsils will show a sympathy of congestion somewhat proportionate to that acutely present within the uvula.

Mackenzie<sup>1</sup> says: "Some cases where the pharynx is inflamed the violence of the morbid action appears to be expended on the uvula." Sajous<sup>2</sup> speaks only of relaxed throat and uvula, which may be caused by chronic catarrhal inflammation; and Heath<sup>3</sup> of oedematous uvula due to inflammation and commonly found in any acute inflammation of the throat. Ingals<sup>4</sup>, in his lectures on the throat, does not mention the subject. Browne<sup>5</sup>, of London, in his recent edition, writes to the point; he says: "The uvula becomes suddenly red, swollen and infiltrated, with comparatively little hyperæmia of the neighboring parts. Cohen<sup>6</sup> notes that oedema uvulæ sometimes occurs during the progress of acute or chronic sore throat, and the organ may acquire the size of a large bean or even that of a plum; and will provoke spasms of impending asphyxia.

The case in question seems to be a unique one and a striking exception to the doctrine laid down by most of the authors consulted. *Case:* Mr. M., a patent attorney, aged 40 years, was on the morning of April 14th in perfect health and had never been treated for throat trouble. In the afternoon, which was clear and balmy, he experienced no symptoms of cold or catching cold. Later in the same evening his throat began gradually and steadily to fill up, and within four or five hours spasms of suffocation attacked him. Patient described it as though his tonsils had fallen and were movable in the throat. Could not swallow anything solid, and liquids with great difficulty. Had no fever, tongue moderately coated, and his daily regulations of life were and had been good. He had eaten a rather heavy dinner about 8 o'clock and had smoked and drunk a great deal, but not to excess. It was not until near 12 o'clock at night that he commenced to feel uncomfortable about his throat. Early the next morning he came to my office, asking to be seen immediately.

Inspection by aid of strong reflected light revealed a limited but intense palatine congestion and an enormous oedematous uvula. The tonsils, palatine folds and pharynx were not hyperæmic, and the patient complained of no pain on pressure externally against the tonsils, nor were they at all prominent to the touch. The uvula was fully the size of the thumb in thickness, and on inspiration and expiration would flap back and forth, sometimes lying as a great pendulous mass on the tongue, and then, on hasty and forcible inspiration, dropping deep in the fauces, setting up a succession of paroxysmal coughs.

With the aid of Ingals' dressing forceps I

grasped the swollen uvula in expiration at its most pendulous portion and made a number of stabs with the bistoury, but finding only little bleeding I used a large needle, held it firmly with the needle-holder, thrusting the point many times deep into the tissues. The oozing of blood and serum was so little, and the swelling having diminished to such a slight degree, after waiting some fifteen or twenty minutes more I determined to try the effect of a strong solution of cocaine. I therefore painted the whole uvula with a 15 per cent. and reapplied within ten minutes. The engorgement now commenced to immediately disappear and was reduced considerably before the patient left the office, he expressing himself as feeling freer and more comfortable about the throat. I ordered a dose of Rochelle salts, a gargle of tannin, aconite and rose-water, to use no warm drinks and to take little or no food, and that of a liquid character.

The same day, six hours after, the patient returned to the office, expressed himself better, and on inspection I found the swelling had subsided fully one-half. Reapplied the solution of cocaine and continued liquid diet. Next day the uvula was almost normal in size; throat perfectly comfortable; patient discharged cured.

I was led to the trial, in this affection, of cocaine, knowing full well its power of readily reducing the turgescence of the mucous membrane in acute affections of the nasal passages. Its use in acute oedematous uvulitis may have been specially recommended; if so, I have failed to find mention among the number of works I have consulted. Laffont<sup>7</sup>, of Paris, speaks of the local effect of cocaine in increasing the functional activity of the sympathetic nervous system, causing contraction of non-striated muscular fibres. Bosworth<sup>8</sup> claims that cocaine produces rigid contraction of unstriated muscular fibres, and that, topically applied, it will so constrict the blood vessels of an acutely inflamed mucous membrane as to arrest the disease. Wood's<sup>9</sup> experience is that in some acute mucous inflammations the primary bleaching is permanent.

To explain this rapid and localized oedema and equally rapid and permanent disappearance, I believe we must look to the vaso-motors as being greatly at fault. The uvula is in direct communication with the stomach, through the sympathetic system. Flint<sup>10</sup> says there can be no doubt that the sympathetic branches contain filaments capable of modifying the calibre of blood-vessels. We can trace the nervous origin by many routes; one among them is through the descending palatine branches into Meckel's ganglion, thence to the sympathetic root, on to the carotid and gas-

tric plexus. But the most direct and easily explainable route is by the afferent branches of the pneumogastric, joining with the filaments to the superior cervical ganglion, branches from which ganglion, forming a plexus on the external carotid artery, are distributed to the ramifications of this artery.

I regard this case as an illustration of a phenomenon acting reflexly through the sympathetic system, localized in its manifestation and operating from the stomach, a function not foreign to the sympathetic nor *contra ideas*, when we remember the important influence which the sympathetic always plays upon nutrition, calorification and secretion.

The rapid course which this disease ran shows, first, how the stomach may reflexly and acutely act upon the upper air passages; second, that by giving rest to the stomach and causing depletion, local and general, we effected a termination of this disease as hastily as it was acutely manifested.

DR. MURRAY: Œdema of the uvula without general congestion of the surrounding parts is not common. It does not occur in Bright's disease, and is found among the sequelæ of the exanthemata. In the aged it is also seen, the result probably of anæmia. The case presented, as interpreted by Dr. Morgan, was in his experience unique. Reflex irritation is the most interesting; the list of disorders directly referable to this agency is receiving constant additions. In the case before us Dr. Morgan has traced with accuracy the several channels through which the reflex may have come, but he has not clearly established the fact that it did not come through any of them; and Dr. Murray did not think it possible to do so. He was inclined to believe that the condition described by Dr. Morgan was directly due to the local irritation produced by the alcohol, which his patient had swallowed the night before. In the beginning there probably was general congestion. The uvula for obvious reasons being more congested than the surrounding parts stasis occurred. When the patient presented himself for treatment he had been moving about for several hours, and had possibly indulged freely in ice water. The general congestion had disappeared, leaving the œdematous uvula to tell the tale. The treatment instituted met all the indications and the result left nothing to be desired. Where there is much œdema the readiest means of getting rid of it is to clip a small portion from the most dependent part of the mucous membrane; if this is properly done it occasions no more soreness than scarification, and is more efficacious.

DR. KLEINSCHMIDT: The condition could be explained upon the reflex theory advanced by Dr. Morgan or the more direct route mentioned by Dr. Murray—either would produce the same result. Either theory would account for the

promptness of relief by the treatment. Cases of œdema from alcoholic intoxication are not so uncommon, but they seldom consult a physician because the œdema passes off in a few hours under the ice water which is usually taken to allay the thirst following a debauch. He had seen two or three cases of enlarged uvulæ with symptoms of suffocation. He does not think the uvula is the only part congested. If the reflex theory was to be adopted, he thought he could trace a route more direct than that given by Dr. Morgan, namely: by way of the glossopharyngeal of the petrous ganglia, which was connected by the filament with the superior cervical ganglia, thence the vasomotor passed to the carotid flexus and supplied the parts involved.

THE PRESIDENT said he had seen a case of scarlet fever in which the throat symptoms had subsided; he allowed the patient to take some ginger ale and the next morning he found the uvula in the condition described by Dr. Morgan. He snipped off a small piece of the mucous membrane and it promptly healed. In a weak and debilitated old lady he found an enormous elongated uvula. He pulled it through her teeth and cut off fully 2 inches of the mucous membrane and she was well in 24 hours.

DR. THOMPSON saw a great many cases of elongated uvulæ with symptoms of suffocation. Not long since a physician came to his office at night because he feared he would suffocate before morning. The uvula was enlarged and elongated. He snipped off a piece of the mucous membrane and relieved him. It was not necessary to cut off much. If we cut off mucous membrane in proportion to the size of the diseased part, we cut off too much, so that when cicatrization takes place there is not much uvula left. He had never tried cocaine, as snipping answered his purpose. He usually used two instruments: Gross' forceps and uterine curved scissors. It was better to cut off a small piece of the mucous membrane upwards and anteriorly.

DR. MURRAY thought the operation best as performed by Dr. Thompson, with scissors and forceps.

DR. HAGNER thought it better to cut upward and backward, to prevent the food from coming in contact with the raw surface.

DR. MORGAN thought cocaine better in women and children, and in nervous persons who would object to the knife.

DR. J. FORD THOMPSON reported

A CASE OF CASTRATION FOR HÆMATOCELE, and exhibited the specimen. Dr. Thompson thought the specimen of sufficient interest to present because the opportunities of seeing such pathological specimens are rare. Dr. M. Muncester had brought the man, aged 27, to him for a tumor of the right testicle. On examination it presented

all the symptoms and had the appearance and history of hydrocele. It was of six years' duration; he attributed it to a fall, but it was slow in its growth, having taken six years to reach its present size. A few months ago he got married, when it occurred to him that he would have something done for it. The tumor was pyriform in shape; no enlargement of the cord; there was considerable induration, which he attributed to thickening of the sac. He detected fluctuation. He introduced a trocar above the middle of the tumor, but nothing came away; he withdrew the trocar, and upon palpating the lower part he detected fluctuation, and again introduced the trocar and drew off about a drachm of a peculiar looking fluid, which the patient likened to "tomato catsup." He now said it was a hæmatocele, and would require a more thorough operation. He had lost all sensation on this side three or four years ago. April 21, he operated under anæsthesia. As soon as the patient became anæsthetized the tumor felt so solid and indurated with spots here and there, of fluctuation, that he changed his view and believed it a sarco-cystocele. He then made a large incision through a dense tissue, which he supposed to be the tunica vaginalis, but which was the tunica albuginea. He dissected this off and castrated, finding the cord normal. The sac was the tunica vaginalis enormously thickened, filled with coagulated blood, which had misled him. The tunica vaginalis was in very much the condition of an old aneurism. It would be seen that the remains of the atrophied testicle were imbedded in the wall of the tunica vaginalis.

The diagnosis in such cases is almost impossible without an incision.

In the treatment of such cases puncture amounts to nothing. Then what is the next best treatment? In an ordinary case of hæmatocele the older writers advised to lay open the sac and let it heal by granulation; and the more recent, to dress it antiseptically. In such cases as this the operation he performed was far better. The other operation for such a case is Volkmann's, which would have made a long illness. The testicle was atrophied and useless to this patient, so there was no object in leaving it. In old men, or those past fifty, there is no question about the operation; in younger men, if the testicle is believed to be normal, it is better to dissect out the sac and let it fill by granulation.

Curling says: "Occasionally the blood is found converted into a solid fibrinous substance, of a yellow or fawn color, arranged in firm layers, similar to the coagula lining the sac of an aneurism.

*Diagnosis.*—In old cases in which the tunica vaginalis and its envelopes have become much thickened and indurated the tumor possesses so firm a character, feels so heavy and solid, that it

is very liable to be mistaken for a chronic enlargement of the testicle; and the diagnosis, at all times difficult, in some cases cannot be made out by the nicest manipulation of the most experienced hands."

Curling gives a personal case which, even better than mine, presents the difficulty of diagnosis in some old cases. A Portuguese, aged 26, consulted him—Curling—for disease of the right testicle. The organ was large, opaque, felt firm, weighed heavy, and afforded an indistinct sense of fluctuation. The enlargement had existed twelve years, but had grown a good deal lately. In expectation of finding fluid, he thrust a fine trocar into the upper part of the swelling, but nothing except a few drops of blood appeared. Mercury was then given to slight soreness of gums, with no effect. Being still impressed that fluid existed, he introduced the trocar into the lower part of the swelling, with the same result as before. A consultation was held over the case at the London Hospital. As a result of the consultation the tumor was strapped and iodide of potassium given for a fortnight; patient rather worse from treatment. At second consultation it was determined to remove the tumor by operation, thinking that it might be cystic. After careful manipulation the testicle could not be placed. An incision was made which passed through the displaced testicle and it was then castrated.

He also gave the notes of a case of death in an old man from opening the sac, which was so thick as to prevent its collapsing. In old men with thickened tissues castration is the best operation.

Erichsen says: If the tumor were of very large size, and the tunica vaginalis much thickened, hardened, and parchment-like, with adherent and laminated fibres, castration might possibly be required. He refers to such a case in which he castrated.

Dr. Thompson had seen a surgeon cut away the tunica vaginalis with the thermo-cautery in a case similar to his. He usually tapped a case of hydrocele and allowed the patient to walk home, but in this case he suspected something more and sent him home. In doubtful cases we should make an exploratory incision and be guided according to what we find.

DR. SMITH asked Dr. Thompson if hydrocele could have been differentiated by transmitted light in this case, or in one with such a thick sac?

DR. THOMPSON: No. He seldom used artificial light in diagnosing hydrocele, but depended upon palpation. If at the time of operation he failed to find fluid by the trocar he would make an incision.

DR. SMITH: This was the second diseased testicle that had been presented to the Society in twenty years. Six or seven years ago he presented a testicle which he had removed for tuber-

cular disease. He had some time previously operated on this man for hydrocele. Soon after he left the city. The tumor recurred and he consulted a surgeon, who stated that the hydrocele had returned; he tapped, but only got blood. Suppuration was then set up and the puncture would not heal. The man returned and consulted Dr. Smith. The testicle was removed and the man gained sixty or seventy pounds in weight. If the testicle had not been removed Dr. Smith believes this man would have died of tubercular disease. Dr. Smith thought that it was very singular that diseases of the analogous organs in the female were so much more frequent, and he did not know how to account for it. Women who abuse their sexual organs, as prostitutes, have ovarian disease requiring operation much less frequently than the virtuous. Why is it that the ovaries are so frequently diseased and the testicles so infrequently?

Dr. Thompson frequently operated on diseased testicles, but only presented unique specimens to the Society. This specimen was very uncommon, hence the interest in it.

## DOMESTIC CORRESPONDENCE.

### LETTER FROM NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

*Dr. Rockwell on the General Therapeutic Action of Electricity—Dr. C. L. Dana defends Static Electricity—Dr. H. D. Chapin on the Auriculo-Ventricular (presystolic) Sound, and Some Considerations on Cardiac Disease in Childhood.*

It will perhaps be remembered that last spring Dr. M. Allen Starr, Clinical Professor of Diseases of the Mind and Nervous System at the College of Physicians and Surgeons, read a paper before the New York Academy of Medicine on "The Therapeutic Value of Electricity," the tendency of which was decidedly to undermine the confidence of the profession in this agent. At the last meeting of the Section on Practice of the Academy an opportunity was afforded to some of those whose views are at variance with those of Dr. Starr to defend it against the aspersions cast upon its good name.

On this occasion Dr. A. D. Rockwell, the well-known expert, read a paper on "The General Therapeutic Action of Electricity." At the outset he said that notwithstanding all that had been written upon electrical treatment, there existed so little correct appreciation of the physics of this agent that it became necessary to emphasize again and again the statement that electricity is not a simple, single manifestation of natural force, but a generic term including complex phenomena and a great variety of manifestations. Much, indeed,

was claimed for it; but it accomplished much and produced effects widely divergent, so that it was often of service in more or less opposite conditions. Later he expressed himself in the following very plain language: "When its therapeutic efficiency is denied, the inevitable conclusion at which those must arrive who have time and time again witnessed evidences of its power is, that he who fails in his results is deficient in his experience, is not sufficiently persistent, or has somehow failed in the technique of his applications."

Electricity, he said, was not only a stimulant of the most powerful character, but it was also a sedative which in certain cases was unexcelled. Furthermore, it was a tonic of a very high order, and to produce the tension of the nervous system and of the muscular fibres generally which would enable them to respond to their natural stimuli, the mechanical effects of the faradic current seemed to be especially applicable. Properly applied, it would not produce any appreciable muscular contractions, and yet it gave passive exercise to all the deeper-lying as well as superficial muscles. Aside from its purely mechanical effects, it was evident that even this current exerted some other and more subtle influence upon the nerves themselves; for by no purely mechanical means could we account for the numerous phenomena that followed its use in diseased conditions. General faradization might be said to be indicated, therefore, whenever a constitutional tonic influence was called for.

This law rendered the remedy as valuable to the general practitioner as to the specialist. For the tedious period of convalescence which often follows typhoid and other fevers there was no remedy that was comparable to it, and in a large number of conditions of depressed vitality electricity in some of its forms would prove of service. In addition to giving passive exercise to the muscles, it rendered more natural the processes of secretion and excretion, corrected circulatory disturbances, and afforded tone and strength to both nerve and muscle. With these general principles in view, he said, we cease to wonder that electricity is used and recommended for such a variety of diseases, and appreciate the injustice of the criticism which condemns it because it is claimed to be of service in so many different conditions.

Having spoken of some of its physical effects, he said that the chemical or electrolytic influences which are associated with electrical action were practically confined to galvanism. Its special utility was in the department of electro-surgery; but it was undoubtedly true that some electrolytic action occurs in all ordinary applications of galvanism to the body, while it was probable that it was a factor of more or less importance in making up the sum of electro-therapeutic effects.

In its influence over nutrition, however, Dr. Rockwell went on to say, the physiological effects

of electricity were perhaps the most important; the action of either current modifying physiological function in various ways. Having mentioned its influence over the salivary and mucus secretions, and its admirable effect in the condition known as dry catarrh, he stated that his experience had been that appetite was sharpened, digestion quickened, and constipation relieved, both by local and general electrical treatment, so rapidly as to make it pretty evident that the gastric, biliary and intestinal secretions were markedly affected by the action of the current on the nerves supplying the organs of digestion. These results had also been recently confirmed by Ziemssen by experiments on animals. Among those affections of the bowels in which electricity was quite certain to exercise a beneficial influence were defective innervation, atrophy of the muscular tissue, digestive atony, and the wide section of diseases comprehended under the name of hypochondriacal and neurasthenic. The effect of electricity in diminishing, and even arresting, the physiological activity of the organs of secretion and excretion was next considered, and the paper brought to a conclusion with some notice of its influence on absorption and its consequent practical value in relieving many hypertrophies, effusions and morbid growths.

At the conclusion of Dr. Rockwell's paper Dr. C. L. Dana read a short paper which was devoted to a defense of static electricity. A recent writer on electro-therapeutics and physics, he said, had referred to electricity as a form of energy. This was a fundamental error, and showed a lack of grasp of the subject which was truly elemental. Electricity was not a form of energy, but a condition of ether in a state of stress or motion. The same critic also spoke of "producing" electricity; which was as absurd as to talk of producing matter. In static electricity the electrical fluid or ether was in a state of strain, like a thin rubber band stretched to its utmost. When the strain was relieved there was a disruptive discharge, as when the elastic band broke. By using small Leyden jars which filled and discharged very quickly the current could be made almost continuous and would cause chemical effects. The static discharge occupied such an exceedingly brief space of time that its intensity or current strength was hardly measurable; but its voltage or electro-motor force was immense.

In describing its physiological effects he said that the muscular contractions caused by static electricity had been stated to be due to a purely mechanical effect, like that of a whip; but this he believed to be an erroneous view for the reason that the sparks caused contraction when applied directly to muscle, while in order that mechanical irritation should cause contraction of a whole muscle, it was necessary that it should be applied at the motor point.

As to its therapeutic uses, he believed that the special advantage of the static battery was in paralyses with some spastic element, as in hemiplegias and paraplegias. Aside from this he said its best results were in chronic muscular rheumatic and neuralgic conditions and in many sensory disorders. It had a specific æsthesia-genetic influence in certain cases; producing effects in a way similar to metal-therapy—not by mental influence or suggestion. It had practically a very great value in dispensary clinics where a good many cases of paralysis had to be treated. In nervous clinics with few patients' and abundant medical attendance the faradic and galvanic battery might answer, and this might explain the indifference to static electricity by some of its critics; but in large dispensaries he considered it almost a duty to patients to have a battery which induced a prompt and efficient electrical treatment in all cases. "Our mastery of disease," Dr. Dana said in conclusion, "is not so great, or our means of attacking it so ample, that we can afford to ignore a single measure that will help us in the fight."

In continuing the discussion Dr. J. H. Gunning spoke particularly of the special value of static electricity in facial paralysis and of the faradic current as an emmenagogue.

At the same meeting Dr. H. D. Chapin read a paper consisting of two sections, the first being devoted to "The Auriculo-ventricular (presystolic) Sound," and the second to "Some Considerations on Cardiac Disease in Childhood." In speaking of the presystolic murmur due to mitral stenosis he said that in some cases it could only be detected after some exercise, and in making his examinations he was in the habit, therefore, of requiring the patient to first jump up and down a few times. The utility of such a precaution was shown by the fact that two individuals in whom he had found the murmur present had been able to secure first-class risks in life insurance companies; the murmur no doubt being imperceptible at the time the heart was auscultated by the medical examiners on account of the applicants being at rest. The prognosis in presystolic murmur he regarded as usually favorable.

In treating of cardiac disease in children he spoke of the well-known fact that rheumatism, ordinarily the cause of such disease, is apt to be very much less severe in children than in adults; the affection not infrequently escaping notice entirely. In his experience he had found that very often cardiac trouble does not occur with the first attack of rheumatism, and sometimes does not ensue until the child has had several attacks of the latter. He also spoke of the much greater tolerance of disease of the heart in children than in adults. In the treatment of such disease he laid stress on the prime importance of early interference and the insistence on complete rest.

In discussing the paper Dr. Andrew H. Smith said that he was not one of those who believe in the existence of a presystolic murmur distinct from the diastolic and having a mode of production and a significance of its own. There was, indeed, a presystolic murmur, but it was only a continuation of the diastolic murmur, reinforced by the contraction of the auricle. If the orifice were greatly narrowed, and especially if it was irregular, the flow of blood through it would cause a sound during the ventricular diastole and before the auricular systole. If, on the other hand, the orifice was less contracted and less irregular, the blood would pass through it silently until its flow was hurried by the contraction of the auricle; when a murmur would be developed. This supplement to the diastolic murmur he believed had no different significance from the latter, and he could see no reason for giving it an especial name. Dr. Smith said his experience coincided with that of Dr. Chapin as regards the tolerance of cardiac disease in early life, and stated that he had seen children who had had severe endocarditis complicated with very marked valvular lesions go on for years apparently suffering but little inconvenience.

Dr. A. L. Loomis said that he did not suppose that at the present day there was any doubt in the minds of auscultators as to the existence of a presystolic murmur. He had been accustomed to consider three classes of presystolic murmurs: the hæmic, the congenital, and those depending on chronic endocarditis. These murmurs were often independent of systolic murmurs, and sometimes were present in addition to the latter. He thought that, in general, we were apt to attach too much importance to cardiac murmurs. To be really of importance they must be accompanied by changes in the cavities and walls of the heart and in other parts of the system; and this was especially true as regards mitral disease.

Dr. E. G. Janeway said that for a long time some authorities hesitated to accept the existence of the presystolic murmur, on the ground that the auricle has not sufficient force to produce such a murmur. It could be positively demonstrated, however, that in reality very little force was required for this purpose. As regards the prognosis of mitral stenosis, his experience had led him to take a somewhat less hopeful view than had been expressed by Dr. Chapin and others.

Dr. J. Lewis Smith said that his experience coincided with that of others as to the comparative mildness of rheumatism in childhood, and he thought there could be no doubt that there were many "walking cases" of the disease. Parents would state that their children had not complained of pain, or if they did so, the circumstance was attributed to "growing pains," and regarded as a matter for congratulation, as indicating an increasing robustness of constitution.

So far from this being the case, however, such "growing pains" were too often the evidence of a condition which caused irreparable damage to the heart. The occurrence of rheumatism was thus frequently overlooked, and hence the opportunity was missed for the employment of treatment which might avert the impending danger of permanent cardiac disease. As to the matter of prognosis in the case of valvular lesions in children, he expressed the conviction that we are accustomed to regard such trouble in too favorable a light. He had found that in many cases dilatation and hypertrophy developed in the course of two or three years, and subsequently the cardiac disease terminated fatally. P. B. P.

### Is Small-Pox Contagious before the Eruption Appears?

*To the Editor:*—A man afflicted with small-pox walked our streets one day last week, causing no small degree of popular and journalistic agitation. A prominent physician who had examined the case is reported as saying: "I do not know that small-pox is contagious in the first three or four days, before the eruption comes out."

I can assure the profession that this malady is contagious in the pre-eruptive stage, and will now adduce a case in point: One night during the year ending July 1, 1872, a young German clerk sought admittance to the Long Island College Hospital, Brooklyn, N. Y. The Superintendent, William V. Blower, arose from his bed to admit the patient, but although not a medical man himself, upon seeing and questioning him he suspected the malady might be a contagious one, and as such were not admissible, he awoke me for advice. Although there was no eruption, at first sight I was convinced the disease was small-pox. The patient's repeated declaration that the only pain he had was a most excruciating pain in the left breast did not swerve me one iota from the diagnosis I had made, and I have always believed in regard to this case that the patient well knew what his malady was—had probably in his mind a distinct history of his exposure, but deliberately lied to avoid being sent to the Flatbush pesthouse.

We sent him to the attic accompanied by a nurse named Emanuel Pinn, aged 18 or 20 years, and at daylight called in our counsel—Prof. S. D. Armor, Drs. William H. Dudley and A. Mitchell. The counsel said: "We agree with you, doctor, that this man has small-pox, yet do not feel justified in sending him to the pesthouse until we see or feel some signs of an eruption coming." Three hours later they came again; there was still no eruption *visible*, but the *shotty* feeling (the feeling as if small gunshots were distributed there) was quite perceptible in the skin of the forehead.

This patient was then sent to Flatbush, and a most serious case it proved, but my recollection is that this patient recovered. Not so with Emanuel Pinn, the man who kept him company a few hours in the attic before the eruption appeared—for I repeat, *there was no eruption visible when the patient left us for Flatbush.* At the expiration of twelve days from the date of his exposure Pinn developed small-pox, was likewise sent to Flatbush, and died there of that disorder. Very respectfully,  
T. J. HUTTON, M.D.

716 Chicago Opera House, November 18, 1889.

## NECROLOGY.

Dr. T. B. Harvey.

Dr. Harvey, one of the best known and highly prized physicians in the country, died very suddenly at his home in Indianapolis, Ind., on the evening of Dec. 5. He was sixty-two years of age, and was actively engaged in the practice of his profession. In the presence of his class, and in the midst of a clinical lecture, in connection with the Indiana Medical College, he was suddenly stricken with cerebral hæmorrhage. He was saved from falling to the floor by the students surrounding him, and was placed in the clinic chair in which he was about to examine a patient. He was immediately conveyed to the adjoining library, still holding with firm grasp the notes of his lecture, and making desperate efforts to continue his address. Almost immediately, however, he became unconscious, and continued so till his death. As a successful medical teacher, Dr. Harvey was widely known and deservedly popular as a consulting physician and surgeon, especially in the surgical diseases of women. His services were greatly valued in the Mississippi valley. He was intimately known in the National, State and local medical societies, and everywhere sincerely esteemed. The sympathies of the profession will be freely accorded to his family, thus suddenly bereaved.

## BOOK REVIEWS.

**THE CEREBRAL PALSIES OF CHILDREN.** A Clinical Study from the Infirmary for Nervous Diseases, Philadelphia, by WILLIAM OSLER, M.D., F.R.C.P., London, Professor of Clinical Medicine in the University of Pennsylvania, etc. Philadelphia: P. Blakiston, Son & Co. 1889. Pp. viii, 103.

This valuable contribution to the subject of cerebral palsies in children is based upon a study of 151 cases of the diseases under consideration. These are divided as follows: Cases of hemiplegia, 120; cases of bilateral hemiplegia, 20; cases

of paraplegia, 11. The writer claims that the amount of material upon which his study is based is much larger than has heretofore been analyzed from any clinic. The cases are grouped in such manner as to illustrate the special etiological factors which appear in each series of cases. The clinical reports themselves are models of terseness and clearness of presentation. No attempt has been made to go into the details of etiology and pathological anatomy, the report being essentially a clinical one. The author is deserving of much credit for the admirable manner in which his subject is offered.

**ELEVENTH ANNUAL REPORT OF THE STATE BOARD OF HEALTH OF THE STATE OF RHODE ISLAND FOR THE YEAR ENDING DECEMBER 31, 1888.**

A reference to the index of this volume will serve to give a good idea of the excellent character of the work being done by the State Board of Health of Rhode Island. The topics are as follows: General Report; Report of the Secretary; Health of the State; Table of Comparative Prevalence of Diseases, five years; Reports of Medical Correspondents; Prevalence of Acute Diseases in the Towns; Reports of Town Clerks in Relation to Sanitary Improvements; Reports of Health Officers; Meteorology; Cattle Commission; Typhoid Fever and its Prevention; Scarlet Fever and its Prevention; Tuberculosis and its Prevalence among the Neat Cattle of Rhode Island; Public Statutes, chap. 83; Additions to the Library.

The articles on typhoid and scarlet fevers and tuberculosis in cattle are of much interest and of great practical value.

**THE MEDICAL REGISTER OF NEW YORK, NEW JERSEY AND CONNECTICUT, 1889-90.** Edited by WILLIAM T. WHITE, M.D. New York: G. P. Putnam's Sons, 1889.

This serviceable little annual, the twenty-sixth of its series, is always welcome. It is a credit to the editor, Dr. White, for his untiring efforts to make it a correct reflection of the *annus medicus*, as each flows by, of the American metropolis and a large adjoining territory. In addition to being a model of completeness and accuracy, it has a healthful policing influence over the quackish elements in medical practice. There has not been a year during the past twenty-six wherein it has not been threatened by some of the "irregulars," or by some whose names are omitted from registration "for cause," but no serious detriment has yet befallen the book from these threats. The book is full of information regarding the hospitals, medical colleges and societies of New York and vicinity. It is useful, reliable, and its *morale* is good, and on these grounds it is thrice welcome.

## MISCELLANY.

**HEALTH IN MICHIGAN.**—For the month of November, 1889, compared with the preceding month, the reports indicate that tonsillitis, erysipelas, measles, membranous croup and small-pox increased, and that diarrhoea, remittent fever, typho-malarial fever, typhoid fever, whooping-cough, dysentery, puerperal fever, cholera morbus and cholera infantum decreased in prevalence.

Compared with the preceding month, the temperature in the month of November, 1889, was much lower, the absolute humidity was less, the relative humidity was more, the day ozone was less and the night ozone was slightly more.

Compared with the average for the month of November in the three years, 1886-88, inflammation of bowels, measles and puerperal fever were more prevalent, and cerebro-spinal meningitis, cholera infantum, cholera morbus and typho-malarial fever were less prevalent in November, 1889.

For the month of November, 1889, compared with the average of corresponding months in the three years 1886-1888, the temperature was higher, the absolute humidity and relative humidity were more, and the day and night ozone were less.

Including reports by regular observers and others, diphtheria was reported present in Michigan in the month of November, 1889, at 69 places, scarlet fever at 71 places, typhoid fever at 83 places, measles at 18 places, and small-pox at 2 places.

Reports from all sources show diphtheria reported at 9 places more, scarlet fever at 17 places more, typhoid fever at 30 places less, measles at 3 places more, and small-pox at 2 places more in the month of November, 1889, than in the preceding month.

*Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from November 30, 1889, to December 6, 1889.*

Major William D. Wolverton, Surgeon U. S. A., Ft. Douglas, Utah, is hereby granted leave of absence for one month, to take effect on or about December 18, 1889, with permission to apply at Hdqrs. Div. of the Missouri for an extension of seven days. Par. 2, S. O. 114, Dept. of the Platte, November 30, 1889.

Capt. John J. Cochran, Asst. Surgeon U. S. A., is granted leave of absence for fifteen days, to commence about December 1, 1889. Par. 8, S. O. 272, Div. of the Atlantic, November 27, 1889.

By direction of the Secretary of War, Capt. James E. Pilcher, Asst. Surgeon, is relieved from duty at Ft. Wood, New York Harbor, and will report in person to the commanding officer, Ft. Clark, Tex., for duty at that station, reporting also by letter to the commanding General, Dept. of Texas. Par. 3, S. O. 276, A. G. O., November 26, 1889.

First Lieut. R. R. Ball, Asst. Surgeon, Ft. Riley, Kan., will proceed to Ft. Sill, I. T., and report to the commanding officer for temporary duty at that post. Par. 2, S. O. 173, Dept. Mo., November 21, 1889.

By direction of the Secretary of War, Capt. John de B. W. Gardiner, Asst. Surgeon, will be relieved from duty at Ft. Reno, I. T., upon the arrival at that post of Capt. James C. Merrill, Asst. Surgeon, and will report in person to the commanding officer, Ft. Supply, Ind. Ter., for duty at that post. Par. 8, S. O. 279, A. G. O., November 30, 1889.

Capt. Walter D. McCaw, Asst. Surgeon U. S. A. (Ft. McPherson, Ga.), is hereby granted leave of absence for fifteen days. Par. 3, S. O. 276, Div. Atlantic, December 3, 1889.

*Official List of Changes in the Medical Corps of the U. S. Navy for the Week Ending December 7, 1889.*

Surgeon J. L. Neilson, detached from the U. S. S. "New Hampshire" and ordered to the U. S. S. "Portsmouth." P. A. Surgeon H. G. Beyer, detached from the U. S. S. "Portsmouth" and placed on waiting orders.

Surgeon C. A. Siegfried, detached from the Naval Station, New London, Conn., and ordered to the "New Hampshire."

P. A. Surgeon Jno. H. Hall, ordered to the Naval Station, New London, Conn.

Asst. Surgeon I. W. Kite, detached from the Naval Hospital, Philadelphia, and ordered to the Naval Hospital, Pensacola, Fla.

Surgeon J. W. Ross, detached from the Naval Hospital, Pensacola, Fla., and placed on waiting orders.

*Official List of Changes of Stations and Duties of Medical Officers of the U. S. Marine-Hospital Service, for the Three Weeks Ending November 30, 1889.*

Surgeon C. S. D. Fessenden, to inspect unserviceable property at Cincinnati, O. November 18, 1889.

Surgeon R. D. Murray, granted leave of absence for thirty days. November 30, 1889.

Surgeon George Purviance, detailed as chairman Board of Examiners. November 20, 1889.

Surgeon J. M. Gassaway, granted leave of absence for twenty-nine days. November 13, 1889.

Surgeon John Godfrey, detailed as member Board of Examiners. November 20, 1889.

Surgeon Fairfax Irwin, detailed as recorder Board of Examiners. November 20, 1889.

P. A. Surgeon H. R. Carter, granted leave of absence for fifteen days. November 27, 1889.

Asst. Surgeon Seaton Norman, ordered to New York Marine-Hospital for temporary duty. November 21, 1889. To examination for promotion, November 22, 1889.

Asst. Surgeon J. B. Fattie, ordered to examination for promotion. November 22, 1889.

Asst. Surgeon F. C. Heath, ordered to examination for promotion. November 22, 1889.

Asst. Surgeon G. M. Magruder, ordered to examination for promotion. November 22, 1889. Granted leave of absence for twenty-seven days. November 29, 1889.

Asst. Surgeon T. B. Perry, granted leave of absence for twenty-five days. November 29, 1889.

Asst. Surgeon J. O. Cobb, granted leave of absence for thirty days. November 29, 1889.

CHANGE OF COLOR IN THE HAIR FROM  
THE INTERNAL USE OF PILOCAR-  
PIN. EXHIBITION OF  
SPECIMENS.

*Read in the Section of Dermatology and Syphilography at the Fortieth  
Annual Meeting of the American Medical Association,  
June, 1889.*

BY D. W. PRENTISS, M.D.,  
OF WASHINGTON, D. C.

In the *Phila. Med. Times* of July 2, 1881, I published a case entitled "Remarkable Change in the Color of the Hair from Light Blonde to Black in a Patient while under Treatment by Pilocarpin. Report of a Case of Pyelo-Nephritis, with unusually prolonged Anuria." This was a case of a lady, 25 years of age, and the drug was used to relieve the uræmic symptoms resulting from the anuria, which latter was extreme.

A record was kept of the amount of urine excreted, and this shows that on one occasion, from December 16 to December 23, a period of seven days, not a drop of urine was passed, and that from January 22, 1881, to February 2, eleven days, there was total anuria.

From January 22 to February 11 (twenty-one days), but 36 grams, or a little over 2 ozs. of urine were passed. During this time the catheter was used twice daily. The uræmic symptoms were very marked and distressing, consisting of dry skin, continual vomiting, severe headache, insomnia, muscular twitchings, confusion of vision, delirium, and threatened convulsions. Hot baths and hot packs did not cause sweating, and gave no relief.

On December 16, 1880, treatment of pilocarpin hydrochlorate hypodermically was commenced, the dose given being 1 centigram (gr.  $\frac{1}{16}$ ). The effect of this was very prompt, and the sweating and salivation produced most profuse. The relief

to the uræmic symptoms was complete, the patient falling into a quiet sleep as soon as the effect of the drug ceased, and sleeping all night, awaking in the morning bright and refreshed. The pilocarpin was thus used twenty-two times from December 16, 1880, to February 22, 1881, requiring 35 or 40 centigrams.

As the patient became accustomed to the medicine it was found necessary to give 2 centigrams at a dose. After February 22 she began to improve, and no more was required.

*Change in Color of the Hair.*—All her life up to November, 1880, the hair was a light blonde. Four specimens of the hair were sent to the editor of the *Phila. Med. Times*, with the report of the case, for his inspection, and were as follows:

"1. November, 1879.

"2. November, 1880.—On both dates the color was the same, a light blonde, with tinge of yellow.

"3. January 12, 1881.—A chestnut brown; and

"4. May 1, 1881.—Almost a pure black."

The growth of hair was also more vigorous and individual hairs thicker.

I believed at the time, and still believe, that this change of color was caused by the pilocarpin. The lady is still at this date (March 10, 1889) under my observation. Her hair is now dark brown, having returned to that color from black. The full report of this case can be found in the *Phila. Med. Times* for July 2, 1881.

The following case is reported, as adding another to the evidence that jaborandi will produce the effect mentioned under favorable circumstances:

Mrs. L., æt. 72 years, suffering from Bright's disease, contracted kidney. Hair and eyebrows have been snow-white for twenty years. Suffered greatly from itching of the skin, due to the uræmia of the kidney disease. Skin harsh and dry.

For this symptom fld. ext. of jaborandi was prescribed, with the effect of relieving the itching. It was taken in doses of 20 or 30 drops, several times a day, from October, 1886, to February, 1888.

During the fall of 1887 it was noticed by the nurse that the eyebrows were growing darker, and that the hair of the head was darker in patches. These patches and the eyebrows continued to become darker, until at the time of her death they were quite black, the black tufts on the head pre-

NOTE.—The specimens presented were as described in the paper. In addition a specimen of the hair of the lady was shown, taken this month (June, 1889), and was nearly black. Dr. Prentiss also showed specimens of the ermine in winter pelt (pure white), summer pelt—white and brown—and in process of change between the two. And also specimens of the bobolink (*Dolichonyx orizivorus*) showing similar changes.

WM. T. CORLETT,  
Sec'y of the Section.

senting a very curious appearance among the silver-white hair surrounding them.

At the time the first of these cases was reported, the facts as stated were received with considerable incredulity, the editor of one well-known Western medical journal openly refusing them credit. Others preferred the charge that the lady had formerly bleached her hair, and that when this was no longer possible her hair returned to its original color.

In reply to these "suggestions," I will only say that the facts are known to scores of people at her home in Washington, D. C., and are entirely beyond question.

As illustrating the ubiquity of the daily press, and the ease with which all sorts of nostrums, valueless or otherwise, may be brought into notice through the newspapers, and how easy it is to make such a matter profitable to the advertiser, I mention an incident in connection with the case just reported:

It seems that some enterprising newspaper man became cognizant of the case, and put a short notice in a New York daily paper, to the effect that a drug had been discovered that would turn white hair black, and make hair grow on bald heads, giving my name as being connected with the Smithsonian Institution.

This paragraph must have been extensively copied in newspapers both throughout this country and abroad. The first intimation I had of its existence was an avalanche of letters from all parts of the country wanting information, some offering money for the receipt, others enclosing money in advance; which latter, be it known, I at once returned.

One from London, England, enclosing the half of a two-dollar bill, with the information that the other half would be speedily forthcoming on receipt of the formula or medicine.

These are the only cases thus far reported in which pilocarpin has been supposed to change the color of the hair.

In 1879 Dr. G. Schmitz,<sup>1</sup> of Cologne, reported two cases in which pilocarpin stimulated the growth of the hair in alopecia. One patient, æt. 60—completely bald. Pilocarpin subcutaneously for disease of the eye. After three injections, within a fortnight, the head became covered with a thick down which grew rapidly, so that in four months no trace of the baldness was left. No mention is made of the color. In the second case the patient, æt. 34, had a bald patch on top of the head the size of a playing card. Total restoration of the hair after two injections, in a short time.

Schöller<sup>2</sup> tells of similar results in animals in whom alopecia had been produced by injections of bacteria.

Oscar Simon<sup>3</sup> relates the case of a woman æt. 30. General alopecia—head, eyebrows, eyelashes, axillæ and pudenda. In a few weeks after twenty injections of pilocarpin the lanugo of the whole body was restored. In other cases so treated there was no effect whatever.

Prof. Pick<sup>4</sup> relates the case of a man who was afflicted with alopecia areolata. Two weeks after pilocarpin injections followed a fine colorless lanugo, and in twelve weeks restoration of the hair. Ten cases of alopecia pityrodes favorable results from same treatment. Color of hair not mentioned.

Landesberg,<sup>5</sup> of Philadelphia, says that in more than 100 cases of eye disease treated by pilocarpin he observed no effect whatever upon the growth of the hair. Dose and mode of administration not mentioned.

In 1882 Julius Pohlman<sup>6</sup> experimented on white rabbits by hypodermic injections of pilocarpin. The dose used was large, 1 grain three times a day. No change in color was noted in pure white rabbits. In particolored animals, white and brown, in one a brown spot on back of head deepened and spread to a remarkable degree down the back and sides of the animal to the legs. In other individuals no change was noticed. Post-mortems in these animals showed enlarged spleen and altered suprarenal capsules.

The question of change of color of the hair is an interesting one both from a physiological point of view and from the practical one of pathology. The physiological aspect embraces the question of how a change of color takes place—whether in existing hairs or produced by shedding of the hair and a new growth taking its place of a different color.

It has been doubted by good authority, Hebra and Kaposi, if the hair, after being once developed, can change except by a very gradual process. This doubt is based upon the theory that the hair has no vascular or nerve connection with the general system, and must therefore be independent of nervous or systemic influence. This position is, however, not tenable. The clinical evidence is positive that the hair does change color under systemic influences—sometimes gradually and sometimes suddenly. We hear frequently of the hair turning white in a night from violent emotions, as fright, great grief or great joy, and it has come to be a method of expressing extreme emotion to say "it was enough to turn one's hair white." I say it is not an uncommon thing to see mention of such cases in popular literature—but well authenticated cases are not so often found. It is recorded in history that the hair of Marie Antoinette and Mary Queen of Scots became white

suddenly from the horrors to which they were subjected. Poets have not failed to avail themselves of the idea. Byron in the "Prisoner of Chillon" says:

"My hair is gray, but not with years,  
Nor grew it white  
In a single night,  
As men's have grown from sudden fears."

A short time since, in conversation with an eminent microscopist and pathologist, I asked how he would explain from the basis of minute anatomy the sudden change in color of the hair. He replied that he did not explain it; that he did not believe it happened; that the reported cases were not authenticated. He further said that from the structure of the hair and its relation to the skin, he considered it impossible.

Duhring, 3d Edition, is authority for the statement that Hebra and Kaposi discredit sudden canities. There is nevertheless no doubt of the fact that such change does sometimes occur, and to set the matter definitely at rest I looked up the subject in the Library of the Surgeon-General's Office. The following are some of the references found:

Dr. Wm. P. Dewees<sup>1</sup> reports a case of puerperal convulsions under his care. From 10 A.M. to 4 P.M. 50 ozs. of blood were taken. Between the times of Dr. Dewees' visits, *not more than an hour*, the hair anterior to the coronal suture turned white. The next day it was less light, and in four or five days was nearly its natural color. He also mentions two cases of sudden blanching from fright.

Dr. Robert Fowler<sup>2</sup> reports the case of a girl 16 years of age, apparently in good health, hair black; found one morning in combing her hair that a strip the whole length of the back hair was white, starting from a surface about 2 inches sq. around the occipital protuberance. Two weeks later she had patches of *Ephelis* over the whole body.

In the *Canada Jour. Med. Sci.*, 1882, p. 113, is reported a case of sudden canities due to business worry. Microscope showed a great many air vesicles both in the medullary substance and between the medullary and cortical substance.

Dr. Graves<sup>3</sup> says most authors are of the opinion that the hair, once formed, is independent of the organism—with which opinion he disagrees, instancing *Plica Polonica* as opposed to such a theory. He gives the following cases:

1. British officer in India, 48 years old, fell into bad health and became prematurely gray. Returned to England, regained his health, and in four years his hair returned to its original brown.

2. In a man 67 years of age, hair white, chest covered with long white hair, chest was blistered, and when hair grew out over blistered surface, it was black.

3. Man æt. 35, bald. Small blister size of crown piece was applied to vertex for congestion of brain. Growth of hair followed over blistered surface.

4. Lady, hair of vertex gray and very scanty. Tar water applied. Hair grew and was of natural color.

5. Same occurred in another case after application of citrine ointment.

In the *Boston Med. and Surg. Jour.*, 1851, is reported a case of a man 30 years old; hair scared white in a day by a grizzly bear. Was sick in a mining camp, was left alone and fell asleep. On waking found a grizzly bear standing over him.

A second case: Man of 23 years was gambling in California. Placed his entire savings of \$1,100 on the turn of a card; was under tremendous nervous excitement while the cards were being dealt. He won. The next day his hair was perfectly white.

In the same article is the statement that the jet black hair of the Pacific Islanders does not turn gray gradually, but when it does turn it is sudden, usually the result of fright or sudden emotions.

The following cases are of change of color from white to black:

Dr. Bruley,<sup>10</sup> physician to the Fontainebleu, reported to the Société Médicale, Paris, in 1798, the case of a woman 60 years old, hair naturally white and transparent as glass, became jet black four days before her death (phthisis). On examination after death the bulbs of the black hairs were of immense size and engorged with dark pigment. The roots of white hairs that remained were dried up and two-thirds smaller in size."

Dr. Alanson Abbe<sup>11</sup> mentions case of Dr. Capen, who had become gray, but on recovery from disease his hair became quite dark.

In the *St. Louis Med. and Surg. Jour.*, 1845, p. 310, there is reported the case of an old man 81 years of age, robust and hale. Hair from being perfectly white became black—same of the beard. This man also presented the phenomena of second sight; could read readily without glasses.

The text-books on skin diseases also mention cases. Several cases of sudden canities are referred to in Ziemssen.

Brown-Séquard in his own person noticed one day a white hair in his beard where there was none the day previous. He pulled it out and the next day others appeared. This was observed repeatedly, and there was no doubt the hair in its entire length turned white in one night. Under the microscope these white hairs showed small air bubbles in place of the normal pigment. In a case of hemiplegia, the hair became white on the paralyzed side. The same has been reported in cases of neuralgia. Other anomalous cases have been noted where the hair became white in patches, and where individual hairs have been seen al-

<sup>12</sup> Loc. cit.

ternately white and black at different stages of its growth—to which condition Karsh and Landois have given the name of “ringed hair,” and ascribed it to an intermittent trophic disease affecting the hair follicle.

Wilson<sup>13</sup> mentions a case where the hair was gray in winter and regained its normal color in summer.

Alibert<sup>14</sup> and Beizel relate cases of women with blonde hair which all came out after severe fever, and when new hair grew it was black. Alibert also relates the case of a young man who lost brown hair during illness, and that which replaced it was red. In the case of an epileptic girl of idiotic type with alternating phases of stupidity and excitement, during the stage of stupidity the hair was blonde; during excitement it was red. This change of color took place in two or three days—the change always beginning at the ends of the hairs. Pale hairs showed an increased number of air spaces. It has been frequently observed that when the hair changes color gradually the change begins in the end and extends toward the bulb. In conversation with an eminent ornithologist on the change of color in the plumage of birds he said: “I have lately been watching hairs in my moustache turn gray, and it always begins at the ends and extends to the roots.”

Speaking on the subject with a lady (the one who furnished the specimens here shown), she mentioned the case of the physician who attended her at the seashore last summer. The doctor's hair was long and quite gray. One day he came in to see her after having his hair cut and she was surprised to notice that the gray hair had given place to black. Examination showed that his hair towards the ends had been white and that nearer the skin black. The white portion had been removed by the cutting.

The cases here collected are only a few in comparison to what might be found; but they are sufficient to prove beyond all reasonable doubt that the hair does suddenly change color under certain circumstances, and that the change takes place in existing hairs.

Analogous to changes in the color of the hair in man are the changes which occur in the lower animals. In animals and birds such changes are often periodical, as in their summer and winter coats. This occurs to a very marked degree in a great many species. Thus the ermine in summer is dark brown, in winter is pure white. Among birds the ptarmigan is white in winter and brown in summer. So with our familiar bobolink, yellow in fall, in spring black and buff. As to the question whether, in birds and animals, this change takes place in individual feathers and hairs, or whether all the old plumage and fur is shed by moulting, recent investigations favor the

view that it is due to both. Dr. Elliott Cones<sup>15</sup> says it may be either or both. Mr. Robt. Ridgeway (Smithsonian Institute) inclines to the opinion that in birds it is accomplished by moulting. Dr. Louis Stejneger (Smithsonian Institute) was formerly of same opinion, but recent studies have inclined him to the belief that there is also a change in the color of existing feathers. He was led to this change of belief by a critical study of the changes in color of the black and white flycatcher of Europe, and especially from an examination of a series of twenty-seven specimens of the narcissus flycatcher (*Xanthophygalia Narcissina*) of Japan. His studies in full will appear in the Proceedings of the U. S. National Museum, 1889. Dr. C. Hart Merriam, Ornithologist of the Agricultural Department, in a letter dated June 12, 1889, says: “The change from fall to spring plumage in birds is due to moult—without exception as far as I am aware. In the case of mammals the matter is now in dispute. Probably in the majority of cases it is due in part to moult and in part to actual change in the color of existing hairs. . . . The change in color from immaturity to maturity is always due to the growth of new hairs or feathers.”

That the change in birds and mammals is due in part at least to change of existing coats seems established. Sometimes this change is almost sudden, as where the change of season is very abrupt. In such case of course there would not be time for the growth of new hair or plumage.

In the golden plover (*Charadrius Dominicus*) the black belly of summer changes to white in winter. While this change is taking place individual feathers part black and part white may be seen. In Bonaparte's gull, a common gull of our coast (*Larus Philadelphia*) the black of the head of summer changes to white in winter principally by change in color of existing feathers.

Another interesting feature of this question as bearing on the change in the color of the hair by drugs, is the influence of certain substances administered as food, in changing the color of tissues in some of the lower orders. In orange canaries it has come to be an established fact that by feeding the parent birds with a certain kind of food the active ingredient of which is cayenne pepper, the offspring will be of an orange color, and orange-colored canaries may be seen in the stores of most bird fanciers. A food for producing orange canaries is extensively advertised by a bird dealer in Baltimore (Bishop). It is reported that the Indians of the Amazon cause green parrots to change to yellow and red by feeding them upon the fat of a certain fish allied to the shad.<sup>16</sup> Dr. Merriam, in the letter previously quoted, says: “It is well known that food affects the color in birds. Red purple finches and pine grosbeaks invariably turn

<sup>13</sup> Drockner, Dis. of Skin, 1888.

<sup>14</sup> Loc. cit.

<sup>15</sup> Fur Bearing Animals.

<sup>16</sup> Wallace's Amazon.

yellow when caged. This is due undoubtedly to the absence of some important food element. In some of the Zoological Gardens of Europe it is the custom to send white spoonbills and flamingoes to Amsterdam Garden to be recolored. The particular food by which Mr. Westermann accomplishes this end is a secret—but it is believed to be a kind of shrimp or small crustacean which has a quantity of red pigment in its shell."

In the same direction are the changes of color in other tissues by particular foods. It has long been known that when pigs are fed on madder their bones become red. This fact has been taken advantage of by physiologists in studying the structure and development of bone. The phosphate of lime acts on the coloring matter of madder as a mordant. When given intermittently to a growing animal, the bone presents alternate rings of red and white.<sup>16</sup>

Darwin<sup>17</sup> mentions that pigs in Virginia eat the paint root (*Lachnanthes Tinctoria*) and their bones are colored pink, and it caused the hoofs of all but the black varieties to drop off. "From facts collected by Heusinger it appears that white sheep and pigs are injured by certain plants, whilst dark-colored individuals escaped. . . . On asking some farmers in Virginia how it was that all their pigs were black he was informed that the black members of a litter were selected for raising, as they only had a chance of living."

Fleurens (1824) made use of madder for coloring the semicircular canals of pigeons, to outline the canals more distinctly. See also Ferrier on "Functions of the Brain," and the writings of Vulpin, the French physiologist. Mr. Lucas, osteologist of the National Museum, informs me that the bones of the crow are made purple by feeding on pokeberries. Ridgway says the bones of the Western fox squirrel are red while those of its Eastern brother are white. No cause has been assigned for the difference.

See also experiments by Marci Paolini in 1841. (Specimen quorundam experimentorum de vi Rubiae ad ossa ovorumque Gallinarum putamina calcariæ coloranda. No. 1 of Miscellanei Medici, Pamphlet Vol. 1149.) He gives a very good plate of the colored skeleton of a fowl, and also of its colored egg after four months feeding *Rubia Tinctorum*. He also gives references to other authorities, the most satisfactory of which is Belchior, Philosophical Transactions, Vol. 9, 1732-44, who gives an account of feeding hogs and fowls with madder root and wheat meal. A rooster so fed died in sixteen days, and showed the condition admirably. Other writers take up the subject after him in the same publication.

It is reported that among workers in cobalt and indigo the hair becomes blue. Also in artisans working with copper, the hair takes a greenish hue.

The color of butterflies can be changed according to the food upon which the caterpillars are fed. More remarkable still, perhaps, is the change of color in the chameleon, and in many insects, according to the color of the substance with which they are in contact.

The environment undoubtedly has a powerful influence upon the coloring of animals and birds. This is clearly illustrated in every museum of natural history. Specimens from arid desert regions are uniformly of a dull, faded appearance compared with those from regions of luxuriant foliage.

M. G. Pouchet,<sup>18</sup> in his work "Mechanism of Change of Color in Fishes and Crustaceans," says that change of color in fishes is due to the size of contractile colored cells placed in the skin. These are under the influence of the nerves. The author found that the particular nerves controlling them (in the turbot) were nerves of the sympathetic system. By cutting the nerve supplying a particular area of the skin, he had been able to retain that area unchanged in color, while the rest changed as the fish found itself on a dark or light surface. That the eye is the means by which this change in its condition is communicated to the fish or crustacean, and that then reflex action takes place through the sympathetic nerves on the color cells of the chromatophors, is proved by the fact that when the animal experimented on is blinded, no further change of color occurs when it is removed from light to dark or the opposite.

Also see *Monthly Microscopical Journal*, 1871, Vol. vi, M. G. Pouchet on "Study of Connection of Nerves and Chromoblasts" (principally in fishes and batrachians).

The reasons assigned by naturalists for periodical change in color of plumage or fur are twofold:

1. Sexual selection.

2. As a protection against enemies.

1. Sexual selection. The male takes on a brighter and more attractive appearance to facilitate the business of courtship and the securing of a mate.

2. As a protection against enemies. In Arctic regions birds and mammals are usually white in winter, the color of the snow, so that they are with more difficulty found by their enemies. Darwin supposes that originally only a few individuals took on this change, and these being better protected, gradually, by a process of natural selection, only the white variety was left.

It is apparent from what has been said that there is very much concerning the changes of color of the hair and other appendages of the skin in man and the lower animals that is not understood. In its normal condition the color of the hair is dependent upon the hair bulb. It is

<sup>16</sup> Todd's Cyclopedia of Anat. and Physiol., Vol. iii, p. 553.

<sup>17</sup> Origin of Species, p. 9.

<sup>18</sup> Trans. of Brit. Assoc. for Adv. of Science, 1872, p. 152.

here that the melanine is secreted from the coloring matter of the blood, and from this point as the hair grows it permeates its cells, the intensity and shades, from black to blonde, depending principally upon the amount of the coloring matter. In black hair the hair bulb is larger, contains a greater amount of melanine, and the hair itself is coarser and of more vigorous growth. In those cases where the hair has turned from white to black, and minute examination has been made, this has been found true.

In the case reported by Bruley, already referred to, of a woman *æt.* 60 whose hair, previously white, became jet black four days before her death, the bulbs of the black hairs are described as being of immense size and engorged with dark pigment, while the roots of the white hairs that remained were dried up and two-thirds smaller in size. So, on the other hand, in change from dark to white the hair is finer in texture, less vigorous in growth, and the hair bulbs smaller.

The sudden change in canities when due to violent emotions, can be explained in no other way than through the bulb. It is true that there is no direct vascular or nerve connection between the bulb and its hair after it emerges from the skin, but it is also undoubtedly true that there is communication by osmosis between the cells of the papilla and those of the shaft and different layers of the hair.

Wilson<sup>15</sup> ascribes the cause of sudden whitening of hair to insufficient nutritive power of the skin; also suggests that there may generate a gaseous fluid in the hair in place of its normal constituents. He says further that the fluids from the blood-vessels of the skin permeate the hair, and thus change in fluids may alter color.

In all of the cases of sudden change to white, where the hair has been examined, the coloring matter has disappeared and in its place is found an accumulation of minute air globules. The same is true of gray hair of advancing age. How the air gets into the capillary structure has never been explained. Two possible explanations are offered. One is that in the destruction of the coloring matter a gaseous substance may be developed. The other is that air may find entrance from without, through the sides or end of the hair. It is possible to suppose a condition of the bulb producing a vacuum in the hair shaft that shall cause, by suction, a drawing in of air. The view that the air finds entrance through the end of the hair is supported in the fact that the change of color begins at the extremity.

*Erector pili* muscle has an important influence on pathological changes which take place in the hair bulb. This minute muscle has its origin in the true skin and, passing downwards, is inserted into the base of the hair bulb, so that when it contracts it lifts the hair outwards and com-

presses its papilla. The effect of sudden fright causes the hair to "stand on end" by contracting this muscle. Temperature has its influence with animals and birds. In cold weather (winter) the change is to white; in summer to black. Cold we know contracts the skin and thus probably causes pressure on the hair bulb. That the hair is easily influenced by external causes, as well as those which come through its bulb, is fully demonstrated. The mere fact that it can be so readily dyed and bleached artificially shows that the agents used for this purpose penetrate its substance. Bleaching agents such as chlorine, peroxide of hydrogen and strong alkalies act by removing the coloring matter, and not by adding any *whiteness* of their own.

It remains to say a few words upon the subject of changing the color of the hair by substances taken internally; and as this paper has already exceeded the limit I had set for it, I shall be brief.

1. In the human subject the only agent, as far as I am aware, which has been charged with changing the color of the hair, when taken internally, is *jaborandi*. Of this sufficient has already been said.

2. Cayenne pepper in changing the color of canary birds to orange.

This is a well known fact to bird fanciers. I tried in Washington to get a specimen to show you, but was told it was not the season for them—that they came in the autumn. Also that they soon relapsed to their original color unless the cayenne pepper food was kept up.

3. The change of color in parrots by the Indians of the Amazon, from green to yellow or red, by feeding the fat of a certain kind of fish (Wallace's Amazon).

4. The restoration of certain birds to their original brilliant colors at the Zoological Garden, Amsterdam, by feeding a kind of shrimp or small crustacean.

5. As analogous to the above, the effect of madder in staining the bones of pigs red, and of pokeberries coloring crows' bones purple.

It might be of interest, did time admit, to study the influence of diet and habit upon the color of hair in different nations of men; as for instance, why the Saxons have light hair and the Gauls black hair. It is within the bounds of possibility, also, that discoveries may be made in the future by which the color of the hair in the human race may be modified by judicious treatment of the parents.

Some colors of hair are not popular, especially with ladies, and it is not likely that cayenne pepper will ever become popular to produce the orange hue. But if its antithesis should be discovered and the orange changed to black or blonde, then perhaps the gentle maiden with auburn hair will disappear, and the white horse be left in melancholy solitude.

<sup>15</sup> Lecture on Skin.

## CLIMATIC CHARACTERISTICS OF SALT LAKE CITY.

*Read in the Section of State Medicine, at the Fortieth Annual Meeting of the American Medical Association, June, 1880.*

BY F. S. BASCOM, M.D.,

OF SALT LAKE CITY.

The members of this Association can easily recall a time when climatological researches were speculative, vague and unsatisfactory, and many of the articles presented on this subject were largely imaginative and conjectural; but within the last decade this subject has engaged the attention of some of the most eminent and scientific physicians, and so many valuable statistics have been collected from the United States Signal Service reports and other sources that climato-therapeutics has become an interesting and important study to every well-informed physician.

Local pride and enthusiasm have, however, induced many writers to advance claims as to the climatic advantages of health resorts which are not justified by actual statistics, nor by the experience of invalids; and though I cannot hope to present to the profession observations especially interesting or original, I do desire to avoid the errors above referred to. Again, there still remains a wide difference of opinion as to what is needed in a health resort. No less an authority than the late Dr. Austin Flint is accredited with having commended to consumptives the wards of Bellevue Hospital; while others, equally honest in their opinions, whose careful researches render them worthy of our consideration, have in turn recommended climates high and low, moist and dry, for apparently the same class of cases. It is hardly to be expected, therefore, that the subject matter of this paper will meet the approval of all; but if I can simply and truthfully present and favorably impress you with a few of the many advantages of Salt Lake City as a sanatory resort, my object will have been accomplished.

Salt Lake City is located near the shores of the Great Salt Lake, in one of the most beautiful valleys of the West. It numbers about 35,000 inhabitants, is laid out in blocks of 40 rods square, with streets 130 feet in width, many of which are adorned with trees and bordered with streams of water. The altitude of the city is 4,348 feet above sea-level. Surrounding the valley are lofty mountain ranges, and one never wearies of the variety of scenery which they afford, the beauty and grandeur of which can hardly be surpassed. The water supply for the city proper comes from the summit of the snow-capped mountains and is pure, clear and cold. Utah lake, 50 miles to the south, is the source of the Jordan river, a stream of fresh water flowing through the city to empty into the Great Salt Lake. This water, however, is only used for irrigating purposes, though the same lake would furnish an unlimited water supply, were it needed. Farms and orchards cover

the valley, and the cereals, fruits and vegetables are raised in abundance. This much as a brief general description of the city and environments, and I will now proceed to the special climatic advantages.

Most authorities believe that the essential features of a health resort, particularly for pulmonary diseases, should be:

1. Atmospheric dryness.
2. Equability of temperature.
3. Altitude varying from 3,000 to 8,000 feet.
4. Greatest number of clear, sunshiny days.
5. Freedom from high winds, electrified storms, etc.

I present them in the order of importance commonly adopted by writers on this subject.

### ATMOSPHERIC DRYNESS.

The dryness of the atmosphere, as indicated inversely by its relative humidity, is, we believe, of more importance to the invalid than any other climatological factor. Dr. Denison, in an interesting essay on this subject, comparing Denver, Col., with Jacksonville, Fla., allowing for the increased volume of air breathed in the higher altitude, due to its rarefaction and consequent frequency of respiration, assuming in both places a robust man breathing eighteen times per minute and expiring an average of thirty cubic inches, ordinary exercise included, shows that in the dry air of Colorado the vapor exhaled above that inhaled in twenty-four hours is 2,453 grains, or nearly six ounces more than during the same period in Florida. The same method of comparison applied to Denver and Salt Lake City shows that in the still dryer air of Salt Lake the excess of vapor transpired would be 144 grains more than in Denver and four ounces more than in Los Angeles. Certainly his suggestion, that "this transpiration of surplus vapor is an admirable vehicle for removing effete matter, waste tissue and germs of disease," is a most reasonable one.

Though opinions vary on almost every other climatic factor, all agree that *pure* air is essential to the invalid, and that the dryer the air, the more aseptic are its properties. This much is conceded by those who oppose altitude, equability, etc., as of importance in climato-therapy. In this connection I would submit the following table, compiled by Dr. H. D. Niles, of this city, from the United States Signal Service reports:

Period of observations, from.	Elevat'n.	Relative	Average	No. clear
1879 to 1884, inclusive.	Feet.	humidity	daily	and fair
		Per cent.	Range.	days.
			Deg. F.	
Salt Lake City . . . . .	4,348	44.0	18.6	277
Denver . . . . .	5,294	51.2	24.2	309
Colorado Springs . . . . .	6,080	55.5	28.4	316
El Paso . . . . .	3,704	48.9	30.1	332
Santa Fe . . . . .	6,902	44.7	26.0	318
Los Angeles . . . . .	371	68.2	23.1	313

It will be noticed that the relative humidity of Salt Lake City during that period is 44 per cent.

of saturation, while that of Denver, a representative high altitude resort, is 51.2, and that of Los Angeles, of low altitude, 68.2, a difference in the first instance, in favor of Salt Lake City, of 7 per cent., while in the latter comparison there is a very great variation of 24 per cent.

Statistics for given periods are apt to be misleading, and in combining the various conditions essential to rating a climate, figures favorable or unfavorable may be chosen, according to the period selected; but, endeavoring to make due allowance for any discrepancies in this regard, I think I am correct in drawing the conclusion that for dryness of atmosphere Salt Lake City is not excelled.

#### EQUABILITY OF TEMPERATURE.

But few authorities are inclined to criticise an equable climate, and this is one of the strong points in favor of Salt Lake. The close proximity of Great Salt Lake, a body of water covering an area of 2,500 square miles, acting as a moderator to the climate and tempering the winds, gives to this city an equability of climate usually found only in low altitudes with excessive moisture. In this feature the climate is indeed unique, and nowhere else, to my knowledge, can the same degree of equability be found combined with perfect hygrometric conditions and such elevation. High altitudes and dry climates usually have their disadvantages in extreme cold, high winds and variability, while to secure equability we must submit to warmth, moisture and accompanying enervation; but in this valley there seems to be a happy exception to the general rule, for, as above indicated, the average daily range is but 18° F. Drs. Hamilton and Standart, well-known Salt Lake physicians, stated, in a recent paper, that from a record of the readings of the thermometer kept at Camp Douglas, three miles from this city, for a period of twenty-four years, previous to the establishment of a signal service station, it was ascertained that the average high extreme for these years was 97<sup>1</sup>/<sub>2</sub>°, and the average low extreme 4° above zero, making an average annual range of 93<sup>1</sup>/<sub>2</sub>°. It will be seen that for equability of climate these figures compare favorably with sanitary resorts of low altitude, while, as compared with cities of the same altitude and relative humidity, there is a marked difference.

#### ALTITUDE.

Another great advantage is that the elevation is not extreme. With an altitude of 4,300 feet, it also has advantages of varying the elevation from 500 to 1,500 feet, for patients may choose their residence either on the benches and foothills of the mountains, or in the valley below, and still be at no great distance from the center of the city. The invigorating and tonic effect of the rarefied air of this altitude, as compared with the heavy, depressing atmosphere of the sea coast,

can hardly be estimated, and certainly none can appreciate it who have never sojourned in a mountainous region. It will also be observed that with a moderate elevation we have nearly all the advantages and none of the dangers of high altitude resorts.

#### NUMBER OF CLEAR AND SUNSHINY DAYS.

Statistics are not so favorable in this respect, perhaps, as in some other cities, and yet it must not be understood that the percentage of cloudy days necessarily indicates that the greater part of the day is cloudy. On the contrary, it is seldom that the sun is obscured longer than a few hours in the day; a fog is unknown, and refreshing rains are hailed with delight. The invalid is soon in the sunshine again, relieved from the dust. A day during which the face of the sun does not smile upon this valley is exceptional indeed, and an event to be remembered. The average rainfall for Salt Lake City from 1847 to 1889 was between 15 and 16 inches, the maximum for any single year during that period being 22.61 inches, the minimum 10.14 inches. Weather reports for a number of years place the mean rainfall at Denver at 14.99 inches, and at Los Angeles, 18.25 inches. A striking advantage in the rainfall of this valley, as compared with Los Angeles, is that while Los Angeles has its rain almost entirely in winter, with but little during the balance of the year, and, consequently, intolerable dust, in Salt Lake City the showers occur during the summer, purifying the atmosphere. *Freedom from high winds*, as already indicated by its equability, is another advantage this climate enjoys. Observations show that the number of miles traveled by the wind at this point for one year was 44,468; some years were as low as 37,000. To more clearly indicate this favorable feature I would state that for the same year statistics show that the number of miles traveled at San Diego was 55,062; Colorado Springs, 70,912; St. Paul, 76,096; Jacksonville, Fla., 74,192, and Cape May, 134,455. This not only relieves from extreme cold, variability, great amount of dust, etc., but what is equally essential, it allows the invalid the freedom of constant open-air exercise, without the dangers of being frozen by a blizzard or translated by a whirlwind, such as are frequent in other high and dry climates. Though this valley may have its dust storms, the moderate velocity of the wind renders this disturbing element less frequent here than usual to corresponding altitudes. But perhaps enough has been said in detail of the climate of this valley, and in what follows I feel that I am justified in assuming that Salt Lake City has the climatic advantages so important to health seekers. Pure and desirable atmosphere is, however, not all-important. Neither is it the only advantage Salt Lake offers. A high and dry climate,

in itself essential, can be greatly aided by healthful surroundings, and if you can add to such a climate many of the beneficial features of a seaside resort, you give to the invalid an "ideal climate" indeed. Such, we believe, is that of Salt Lake City. So large a body of water as the Great Salt Lake lends its modifying influence to the atmosphere of the city, and residents in this valley are invigorated by bathing in its waters, unique and wonderful in their effects. This lake is about 350 miles in circumference, and picturesquely located. Analyses of the water vary in its solid ingredients from 15 to 30 per cent., according to different periods of examination. This may be accounted for by increased fresh water supply at one time, and diminished supply, rapid evaporation, etc., at another. The water is so clear that objects at a depth of 15 feet can be distinctly seen. The temperature of the water during the bathing season (from May 15th to October 15th) varies from 65° to 85° F. The novice need have no fear of going to the bottom, for the density of the water (about 1,800 grains of solid matter to the pint) renders sinking impossible and swimming a delightful exercise; while invalids too weak to indulge in this recreation can spend their time upon the beach, enjoying the sunshine and the beautiful scenery, strengthened by the refreshing breezes of the lake. Eastern cities are filled with men and women enervated by overwork and mental strain, who would be given a new lease of life by one season at the Great Salt Lake, and many consumptives have already attested its virtues and sounded its praises.

We hear of the hot springs of Arkansas and their favorable effects on the many invalids who visit them, but within the limits of this city are several hot sulphur springs of equal virtues, where one can derive all the benefits of the waters without endangering health by the depressing influences of the Arkansas climate. Numerous cases of rheumatic and neuralgic affections, gastro-hepatic, skin and syphilitic diseases, and miners suffering from metallic poisoning, resort to these springs and are benefited by their use, and at an early date it is expected that a sanitarium will be erected in the heart of the city, with all the conveniences for invalids, with baths supplied by piping water both from these springs and Salt Lake, so that all can, with little exertion or expense, derive the full benefit of the springs without inconvenience or loss of time. But the more practical may ask, what class of cases are most benefited by this climate?

I have in my possession a long list of clinical notes on cases of phthisis, etc., which have been cured by this combination of nature's remedies. Some of these histories are of unusual interest from their long and faithful but unavailing trial of other resorts; others because they are the only

survivors of large families which have succumbed to the disease. If any present are interested, I shall be glad to furnish them; but it is not my intention to embody, in an article of this character, elaborate clinical statistics, nor to attempt to classify the diseases which are benefited by a residence in Salt Lake City. I have already, in referring to the lake and springs, indicated some of these diseases, and I might add to such as have been suggested the whole list of so-called strumous affections, while others will suggest themselves to every experienced physician.

Any person taking the trouble to investigate will find that phthisical patients have been and are now being positively and permanently cured by long residence in this climate. I would emphasize the expression "long residence," for many can tell the sad story of some bright young consumptive who has been so greatly improved by a short residence of from three to six months in this climate that the cautions of his friends and physicians are disregarded and he returns to his Eastern home only to find, after a brief interval, that the dread disease is again upon him, and though he may again hasten to the mountains, he finds that it is too late. It is well known that high altitude and rarefied atmosphere accelerate the circulation and hasten tissue change, and the general inference has been that heart disease and advanced cases of lung troubles should be prohibited these climates. Assuming that this inference was correct, I have watched my cases of organic heart disease with much anxiety, and have frequently urged lower altitude. To my surprise, however, some of the most aggravated forms of valvular heart disease are improved rather than depressed by this climate, and among these are patients who have had all the advantages of low altitude resorts and are capable of judging of the relative benefit derived by residence in various altitudes.

In this connection it may be well to again call attention to the moderate altitude of this city and the opportunities for varying the elevation as may be most suitable to the individual case. I offer this suggestion for what it is worth. I do not assume the responsibility of recommending this climate for all cases of heart disease, but it is probable that many cases which do not do well in other climates will progress favorably here.

Again it is presumed that advanced stages of phthisis are not benefited by high altitudes, but the end only hastened. Certainly this is true of extreme and hopeless cases, and yet we are not without many authentic histories of relief and cure in this climate where abscess and well-marked destruction of lung tissue had been diagnosed by our most eminent Eastern physicians, and it is nothing unusual to meet now comparatively healthy and active business men who were brought here on a stretcher. It is, however, im-

portant to impress upon all physicians recommending patients to this climate the desirability of sending them early in the incipency of the disease, if the best results are to be expected. In recent years the many allurements of the Golden State have attracted so many health seekers, and the travel in that direction has been so great that, as when in olden time "all roads led to Rome," so now California is in all instances the objective point. As these people journey homeward disappointed, as a great many are, by the climate of the western coast, we are convinced that they may find in the Great Salt Lake Valley all the climatological factors so essential to the comfort and restoration of the invalid.

DR. H. B. BAKER criticised the author in that he had given only the *relative* and not the absolute humidity, and had not supported his claims with tables of sickness and death.

#### REPORT OF CASES OF DANGEROUS MIDDLE EAR AND MASTOID INFLAMMATIONS WHICH FOLLOWED TREATMENT OF THE NASO-PHARYNX.

*Read in the Section of Laryngology and Otology at the Fortieth Annual Meeting of the American Medical Association, held at Newport, June, 1889.*

BY J. L. THOMPSON, M.D.,  
OF INDIANAPOLIS, IND.

Seventeen or more years ago, when the nasal douche was in the hands of nearly every one under treatment for catarrh, inflammations of the middle ear from the unskilled use of said douche were frequently met with. Now again, since such great advancement has been made in the line of nasal surgery, we see these inflammations quite often. Many of them have fallen under my care of late, some of which are briefly reported as follows:

*Case 1.*—Suppurative otitis media, with total loss of the left memb. tymp., from the use of finely powdered acetate of lead in epistaxis.

This occurred in a young man aged twenty-three years, eight months before he consulted me. He stated that everything had failed to arrest the bleeding until his physician applied the lead, which had the desired effect very quickly, but that it started a violent pain in a few hours, which finally caused perforation and destruction of the drum-head and a discharge ever since, and terribly impaired hearing, which condition still existed at the date of my examination.

*Case 2.*—Otitis media, with extension to mastoid process, following the application of a strong solution of nitrate of silver to the nares. Wild's incision. Apparent recovery. Death.

This happened in a young man aged eighteen,

who had been under treatment by his physician for catarrh for some time. Like the former case, after the use of the silver the ear soon became violently inflamed, was treated, became better and worse, and was finally sent to me for treatment. I found the tissues swollen behind the ear, and immediately cut down to the bone and evacuated a large quantity of pus. He soon became much better and returned home in one week, but took a relapse in a short time and died of meningitis, as I subsequently learned. No post-mortem examination.

*Case 3.*—Otitis media, following the application of caustics to the nasal mucus membrane. Puncture of the drum-head; recovery.

This was in a man sixty years old who was under the care of an eminent specialist of an adjoining state. He suffered very much for weeks but recovered his hearing.

*Case 4.*—Suppurative otitis media of five years duration, following local applications to the nares. Loss of left drum-head, polypoid growths, caries, death.

A young lady, aged twenty, who had been in the hands of an excellent surgeon in another city. He had first treated her nose, then her ear, had removed a polypus, but still there was an offensive discharge, for which she consulted me. I saw a polypus in the middle ear, but as she could not then remain for treatment, gave her a weak solution of bichloride of mercury ( $\frac{1}{4}$  grain to the ounce,) to use once or twice a day until she could return for treatment. She came back in three months, when no sign of a polypus was seen. (This is by no means unusual after the use of bichloride of mercury.)

The dry boracic acid treatment was begun, but it had no effect in stopping the discharge; other applications were made with like results. Carious bone was felt with the probe, which we intended to remove, but as she was called home suddenly owing to the death of an intimate friend, a simple antiseptic wash was given her until she could return, but she died in a very few days from what her physician pronounced to be meningitis.

*Case 5.*—Suppurative otitis media, with total loss of the right drum-head, with greatly impaired hearing following the surgical treatment of the naso-pharynx.

This was a very painful and protracted case from an adjoining State, which had also been in very skilled hands. He had had some nasal hypertrophies removed when a violent inflammation of the ear was set up, was treated for it for some time by the operator, and subsequently by one who made a specialty of the ear, but having a slight cessation of pain he visited relatives in Indianapolis and called on me. I found great tenderness all around the ear, though there was profuse suppuration. He was twice leeches very

freely, when he became much better; tenderness came up again over the mastoid process, but leeches and anodynes to said process and to the external auditory meatus again relieved him. Still much suppuration continued, and I lost sight of him as he had to leave the city.

*Case 6.*—Inflammation of middle ear in a man aged forty-five, following the removal of nasal hypertrophies by caustics. Treatment: leeches, hot fomentations, atropia, to external auditory meatus. Recovery in four weeks.

*Case 7.*—Severe otitis media on both sides in a child twelve years old, following excision of the tonsils. Recovery in three weeks after the free use of leeches and atropine solution.

*Case 8.*—Suppurative otitis media, with perforation of the left memb. tymp., in a young lady aged twenty-two, following the use of caustics to mucous membrane of the nose. Violent pain. Treatment: leeches, atropia, hot fomentations; partial recovery, relapse; hearing finally restored to  $\frac{1}{3}$ .

This lady declares that she had never been troubled with her ears before the treatment of her nose and throat had been begun; but on questioning her very closely she admitted that she had noticed a ringing and buzzing in one ear for a year or more before she consulted a throat specialist.

*Case 9.*—Suppurative otitis media, both sides, of very long standing, with extension of inflammation to mastoid antrum, from local applications to nares. Trephining the bone, followed by perfect recovery and restoration of hearing.

This was a young man aged twenty, who was brought by his physician to see if anything could be done to prevent the frequent relapses of acute inflammation and stop the discharge. On May 10, 1887, one could not touch the tragus nor draw the pinna backward without causing intense pain. The ex. aud. meatus was still very much swollen. Leeches were applied and hot solution of atropia was dropped into the meatus, after thorough gentle cleansing, and he got relief. He was brought from time to time to my office until July 10, 1887, when he complained of dizziness and vomiting occasionally. Much tenderness and redness was found at the back of the ear, and the auricle stood out a little too prominently, but the discharge of pus from the meatus was still copious. An incision was made down to the bone, which was perforated to the antrum with a large drill, when pus followed to the extent of half a tablespoonful. He immediately returned home, and his physician informed me that the discharge ceased and improvement took place immediately. He went to his work in two weeks, and when he came to pay me on September 26, 1887, the drum head was healed. His acuity of hearing  $\frac{1}{3}$ , and he declared his hearing was as good as ever.

*Case 10.*—Suppurative otitis media, with per-

foration of both membranes, in a man aged 25, following the use of a caustic to nasal hypertrophic tissue. Very severe pain, long continued. Treatment, leeching. Hearing finally restored.

*Case 11.*—Was very similar to the above, from the same cause, in a man aged 45; but in this one permanent destruction of both drum heads followed, with greatly reduced hearing distance. He was treated by a physician related to him by marriage, which of course made it rather unpleasant for both parties concerned.

*Case 12.*—Suppurative otitis media, left side, with perforation of drum head, in a lady 23 years of age, following the use of caustics to nose. Long continued inflammation and suppuration, with final recovery of hearing.

*Case 13.*—Suppurative otitis media in a young lady 22 years old, during the treatment of "nasal catarrh." Perforation of drum heads, long continued suppuration, recovery left, extension to mastoid right, symptoms alarming; trephining of bone, rapid recovery, with complete restoration of hearing. She was brought by her physician on the 1st of April, 1888, with a profuse discharge from both ears which had defied all his efforts to control, and which seemed to promise nothing better in my hands for a while; but ultimately the left ear recovered. Late in May she had vertigo, constant vomiting for twenty-four hours, with intense headache. She was placed under an anæsthetic, the left mastoid process cut down upon and perforated by a large drill, which passed into the cavity with a jolt. Much pus followed. A drainage tube was inserted, and it was, of course, dressed antiseptically. The discharge immediately ceased from the ear. In one month she was well, and her hearing is now as good as before any throat or nose treatment had been entered upon.

*Case 14.*—This was an ordinary case of otitis media, with destruction of the drum head and subsequent suppuration, in a young married woman, following the local use of medicines to the nose for hypertrophic catarrh. Sickness of one of the members of her family took her from me, and I have not been able to hear the result.

*Case 15.*—Was very similar to the above, from the same cause, in a lady aged 24. After long treatment the discharge ceased and her hearing was almost as good as before.

*Case 16.*—Ulcerative otitis media in a man aged 38, with perforation of both memb. tymp., following the removal of nasal hypertrophic tissue. Treatment of no avail, hearing very much impaired. I simply saw him a few times after his hearing had been affected; first about three months afterwards, when he was bewailing his sad condition. He said nothing ailed his ears until his nose was treated. He could not then hear a watch unless pressed against each ear. Nothing that I could do benefited him. Again,

in six weeks, he came, but was no better. He was a very quiet, nice German; was so terribly depressed about his hearing that I should not be at all surprised to hear of his committing suicide.

*Case 17.*—Suppurative otitis media in a man aged 44; local applications for severe nasal inflammation. He recovered under leeching and atropia. Hearing as good as before nasal treatment.

*Cases 18 and 19.*—Were both cases of suppurative otitis media. In each did perforation of one memb. tymp. take place; both occurred during treatment of the nose. One recovered after three weeks of treatment; the other still has a discharge from the middle ear, with hearing very much impaired.

*Case 20.*—Differs from all the preceding ones. A delicate-looking woman, aged 33, was brought to me by a throat and nose specialist on account of her terrible complaints concerning her ears. He had removed some hypertrophic tissue from the nose, when she set up a terrible outcry about pain in the ears. I found that some inspissated cerumen prevented a view of the lower part of the ext. aud. meatus on one side. I gently removed this with a syringe, when the woman declared that I almost killed her, and she had to lie down. I gave her a solution of cocaine and atropia to put into the ear, and requested them to call the next day; but just as daylight began to dawn on the following day her husband awakened me, declaring that she was almost frantic with pain in the other ear. He had given her several one-sixth grain doses of morphia, which only partially relieved her. I ordered him to discontinue the use of morphia internally, supposing that she was addicted to its use, which he declared was not the case; that, on the contrary, she was religiously opposed to it. I gave him a simple solution of morphia to drop into the ear hot, apply hot fomentations, etc.; but he was soon back, declaring that his wife was tearing her hair with pain; that pains darted to her uterus, which hurt her just as badly as did the ear, and that it was all the result of the strong treatment which the throat specialist had used. I informed him that I could not continue the case, as it required that a physician visit her, which I could not do. Judge of my surprise when I found her walking into my office in one hour subsequently, feeling much better. On examining the ears I found every evidence in each of an old perforation of the drum head. I have not seen the case since, but have learned from the physician who first brought her that she is a hysterical morphine eater who came very near rendering his life a burden until he expressed his mind to her in as forcible language as the dignity of our profession justifies in such cases.

#### REMARKS.

While engaged in writing up these cases many

similar ones have come under my treatment; indeed, not a week passes that I do not meet with at least one acutely inflamed middle ear, alleged to have been caused by applications of medicines to or operations upon the mucous membrane of the nose or pharynx.

This convinces me that such inflammations from said causes are of very frequent occurrence. Whether or not it is by direct continuity of tissue, or reflex, as claimed by Dr. Woaks, I shall leave to the judgment of my audience, my object being simply to record what I have seen, with a few suggestions as to the course to be pursued in anticipation, prevention and treatment of these exceedingly unpleasant and annoying complications.

Seeing, then, that such cases must be met with occasionally, it behooves every nose and throat specialist to make diligent inquiry of every patient by whom he is consulted as to the condition of his ears. He should not take the statement, "Oh, my ears are all right," but should test them with watch or acumeter and tuning fork; should ascertain the true condition of the drum head as to brightness or dullness, mobility, etc.; should particularly inquire about tinnitus, "stuffed feeling" in ears, etc.; and, above all, should not only keep in mind the fact that few ears remain perfectly normal when nose or throat disease is present, but should also so inform his patient. If this was done more often, the result would be better to the feelings of both patient and medical adviser.

*Second.*—Operations should never be made upon nor caustics applied to nose or pharynx during acute catarrhal inflammation of the parts.

*Third.*—Patients should be requested to report to us immediately on the first twinge of pain in the ear after these applications or operations have been made, so that we may combat them at the very inception.

*Fourth.*—The operator should be prepared to leech such cases early, as time is of the greatest importance. Many of these inflammations could be stopped almost immediately by this alone. He should also be ready to puncture the drum head before it is done by inflammatory action, and he should by no means delay the operation of perforating the mastoid process when extension to it has taken place; for, like the operation of tracheotomy, it is much more often delayed too long than made too early; and we must not forget that opening the bone often immediately relieves the patient of an exceedingly unpleasant and annoying discharge from the external auditory meatus.

It is well also to bear in mind that in the performance of this operation careful surgeons have done just as much with trephine and drill as have others with chisel and mallet, to say nothing of the elegance of the procedure or of the malposi-

tion of the transverse sinus, which could not be injured by skilful manipulators, no matter what instruments were handled.

DR. HOLBROOK CURTIS said that he objected to accepting the statistics as set forth in the paper, from the fact that Dr. Thompson did not state in what manner the caustics so frequently spoken of were employed, nor by whom employed; certainly by no rhinologist who was competent. He thought it was a serious reflection upon methods which are now in vogue and generally recognized as conservative and beneficial, and from which a long line of patients who are now suffering from chronic otitis media and tinnitus are destined to receive relief. The great future of rhinology lies in this especial direction, and to one who has had an experience of several thousand cases in which erectile tumefactions have been treated with chromic acid, and in but one case an acute otitis media observed, it comes upon one as a thunderclap to hear so many cases tabulated as being the result of rhinological work. Every rhinologist sees cases which have been maltreated by the use of caustics in incompetent hands, and the inference one must draw is that in certain localities there must exist a very ignorant class of rhinologists.

DR. E. FLETCHER INGALS, like the gentleman who had just spoken, thought middle ear disease extremely rare as the result of treatment of the nares by competent rhinologists. He could only remember one case, which came on ten days after a severe operation on the septum, and he doubted whether there was any connection between the two. However, he thought the paper well timed and exceedingly valuable.

DR. WOOLEN: I arise to say, first, I am one of those doctors who lounge around Indianapolis, and recognize in the paper two or three of my cases, especially the last; second, my experience teaches me, as does the paper of Dr. Richardson, that many of these cases follow very slight causes and not after formidable operation and cauterization. I have never had them follow a formidable operation, but, as in my last, a small cauterization of anterior tips of inferior turbinated, and fourteen days after, following an exposure in a mine; and, third, that I never cauterize the posterior region of the nose, as suggested by some of the speakers. This is the region for the snare, and should never be subjected to the cauterization, as suggested.

WE regret to learn that Dr. Thomas Opie, Dean of the College of Physicians and Surgeons at Baltimore, and one of the most noted surgeons in the South, is lying dangerously ill from blood poisoning at his home in that city.

## DISEASES OF THE ANTRUM.

*Read in the Section of Oral and Dental Surgery, at the Fortieth Annual Meeting of the American Medical Association, June, 1889.*

BY WILLIAM CARR, M.D.,

OF NEW YORK CITY.

In the preparation of this paper, it was not deemed necessary to describe the anatomy of the maxillary sinus or to mention all its pathological conditions, as the principal end in view was to present in a practical manner a few observations on that form of antral disease that is of especial interest to us as oral surgeons, namely, suppuration. Different authors vary in opinion regarding the causes leading to suppuration. The throat specialist and the dentist view this disease from the standpoint with which each is most familiar, and it is difficult to form an accurate estimate of the specific causes that produce the greatest number of cases. Zuckerkandl, in his treatise on "The Normal and Pathological Anatomy of the Air Passages," claims that a majority of the cases of suppuration of the maxillary sinus directly result from "the extension of the inflammatory process of the nasal mucous membrane, produced by continuity of tissue." That is to say, that rhinitis, either chronic or acute, may cause an inflammatory condition of the sinus and consequent suppuration. Zuckerkandl further says: "My experience with the inflammatory diseases of the lining of the maxillary sinus is, that they mostly follow pathological processes of the nasal mucous membrane, and accordingly the soft parts of the nasal and maxillary cavities are generally diseased together." This view is coincided with by a number of authors. From the advance sheets of Dr. Bosworth's new work on diseases of the nose and throat, I notice that he holds different views. He maintains that few, if any, cases can be traced directly to this cause, claiming that inflammation of the mucous membrane shows but slight tendency to extend from one anatomical region to another. This is doubtless true—we have all observed that an inflammatory condition of the mucous membrane of the oral cavity, although severe, seldom extends to other anatomical regions. As an argument to sustain his theory, Dr. Bosworth states that "but few persons suffer from antral disease compared with the great numbers who are affected with chronic rhinitis." At the same time, he admits that, in many cases, hypertrophic rhinitis produces antral disease—not by extension, but, because this hypertrophic process, in some manner, causes occlusion of the ostium maxillare.

Watson, of London, on "Diseases of the Nose," expresses the opinion that nasal polypi are the most frequent causes of suppuration of the maxillary sinus, from the fact that, in nearly every case, they originate near the ostium maxillare, and, as they develop, they produce an occlusion of the orifice.

Boerhave's researches show that "in its normal condition, the antrum contains a bland, inodorous, gelatinous, colorless fluid;" that this secretion keeps the walls moist, but does not accumulate in the sinus, it being partly absorbed, and, possibly, partly evaporated by the passing air current.

But, should causes operate to close the orifice of the sinus, the external air could not penetrate into it, nor could the air already in the cavity escape from it. In this case, the vascular system would act as a medium for the gradual absorption of the confined air, which would, necessarily, be replaced in the sinus by the secretion. But, as this secretion could not be absorbed as rapidly as exuded, the air yet remaining in the cavity of the sinus would decompose the accumulated mucus, thereby causing irritation and disease of the mucous membrane.

Thus, by closure of the ostium maxillare, it is possible, for the antrum to become diseased, and with its increased secretion, to produce ectasis of the sinus.

From this we can readily understand how nasal polypi and chronic rhinitis may, in many cases, produce antral disease. While I admit that antral diseases are produced by these causes, yet I am convinced, from the number of cases that have been under my immediate observation, that fully 80 per cent. of the cases of suppuration of the antrum are caused either directly or indirectly by diseased teeth. When we consider the anatomical relation of the teeth to the antrum, that they are separated only by a thin layer of bone, and, frequently, the roots of the teeth form protuberances in the floor of the antrum, or actually penetrate into it, when we consider the vascularity of the alveolar process, and the frequent pathological changes of the teeth and their alveoli—these changes being pericementitis, alveolar abscess, alveolar periostitis and necrosis, we can easily comprehend why diseased teeth cause such a large percentage of antral disease.

The symptoms of antral suppuration vary with the exciting cause. When the ostium maxillare is closed either by hypertrophy, nasal polypi or inspissated mucus, the first symptom may be only slight febrile disturbance; but the disease is often ushered in with intermittent fever and rigors accompanied by violent pains, a sense of weight and pressure in the sinus, with distension of its walls, soreness of the teeth and cedema of the cheek. If the suppuration is due to defective teeth, the above symptoms are usually absent, excepting the copious discharge from the nostrils. The natural orifice into the meatus is usually found unobstructed, and the mucous membrane of the facial surface greatly congested as in severe cases of pericementitis. After diagnosis has been established, the treatment of antral suppuration is simple in its character. If caused by

obstruction of the ostium maxillare, the obstruction should immediately be removed, and an effort made to effect a cure through the nares. Should this be unsuccessful, the question arises: Where shall an opening be made for evacuating the sinus of the accumulated secretions, and for subsequent treatment? Various operations have been suggested for this purpose. Owing to a natural hesitancy to remove sound teeth, it has been suggested that an opening be made in the meatus below the inferior turbinate bone. I believe this operation is unjustifiable. While the opening may be made without difficulty, it would be repugnant to the patient, the operation seeming to the patient to be more formidable than it really is. Neither would it afford the same facilities for thorough cleansing as would an opening through the alveolus. I should never hesitate to make an opening through the alveolus even at the sacrifice of a sound tooth, and, in such a case, should be governed in my choice of extraction by the character of the tooth, always selecting the weakest. By preference, I should extract the second molar, as this makes an opening nearer the centre of the floor of the antrum; but if either the first or the third molar, or the second bicuspid is defective, I should remove it. Should it seem best to extract the second bicuspid, I should drill upward and slightly backward, as, at this point, the floor of the antrum is thicker than at the other points mentioned. In case the teeth on the affected side are all missing, I should select the point corresponding to the second molar. If the trouble arises from decayed teeth and necrosis is present, all necrosed bone should be removed. Before commencing either to remove necrosis or to make an opening into the antrum, a 10 per cent. solution of cocaine should be applied to the gums three or four times in order to produce local anaesthesia of the mucous membrane. The operation is then performed with but slight inconvenience or pain to the patient. The opening being established, the antrum should be thoroughly cleansed with tepid distilled water, to which a little salt has been added, until all traces of pus have disappeared. If the discharge is offensive, the cavity should be syringed with permanganate of potash, and dressed with a stimulating solution composed of carbolic acid 1 drachm, glycerine 1 ounce, and distilled water 7 ounces. Or, if preferred, Dobell's solution or Listerine may be applied. The cavity should be cleansed twice daily with salt water, followed by either of these stimulating solutions until the discharge diminishes, when this treatment once daily will be sufficient. Should the orifice in the meatus be closed by inspissated mucus, the patient should be instructed to use either of the above stimulants several times daily, by means of a nasal spray, until the obstruction is removed.

Some practitioners insert a silver drainage tube

through the orifice, which is kept in place by ligatures. I see no advantage to be derived from this practice, as thorough cleansing twice daily is all that is required. Besides, there is always the possibility of food being pressed through the tube into the sinus, or of becoming clogged at the entrance, so that the end sought is not attained. I prefer the method suggested by Dr. Abbott, of closing the opening by means of a broom straw, serrated and wrapped with carbolized cotton, then pressed firmly into place, and retained by ligatures to the teeth. If there are no contiguous teeth, a plate may be inserted with a projection one-half the size of the orifice, and this projection wrapped with carbolized cotton to fill the remaining space. This is sufficient to exclude all foreign substances. After the discharge ceases, the cotton should be diminished in quantity daily, thus permitting the orifice to close gradually. This is the only treatment that I have used, and it has been uniformly successful. The following is a brief history of a few typical cases that I have treated :

*Case 1.*—Mr. M., æt. 33, who stated that, until within two years, he had been in perfect health. He then noticed an offensive discharge from the right nostril which usually disturbed him greatly upon retiring, causing violent coughing when lying upon the left side. Also, upon arising in the morning, he experienced nausea, which continued until the nasal cavity had been entirely cleared. He supposed that he was suffering from catarrh, for which he sought and received treatment, at intervals, for twenty-two months, when the following additional symptoms were manifested : At intervals of three or four days, he experienced attacks of vertigo, followed by severe otalgia, and great tenderness of the teeth. For these symptoms, he was treated by his family physician for three months, who finally advised him to consult me regarding what he supposed to be an alveolar abscess. The right side of his face was then greatly swollen. Upon examination, the full number of teeth were found, but the second bicuspid had been filled, and was pulpless. My diagnosis was not that of simple alveolar abscess, but of suppuration of the antrum. The extraction of the second bicuspid was followed by a slight flow of pus. A further examination showed the alveolar process greatly necrosed, but there was no visible opening into the antrum. After an application of cocaine all necrosis was removed and an opening made into the antrum, when a great quantity of offensive matter escaped. The lining membrane of the antrum had thickened to at least ten times its normal thickness ; this pathological condition I have found in all chronic cases upon which I have operated. Upon proceeding to syringe the sinus, I failed to establish an outlet through the opening into the nares. The sinus was first

cleansed with salt water, then with permanganate of potash, after which the orifice was closed in the manner already described. The patient was then directed to use Dobell's solution by means of a nasal spray, in order to remove any secretion from the nares. The following day, the pledget of straw and cotton was removed, when the discharge seemed greater than on the previous day. The opening through the meatus had by this time been established, and the cavity was thoroughly syringed with hot water until all traces of pus had disappeared. Then it was cleansed with a stimulating solution and the pledget removed. This treatment was continued daily for three months, when the case was cured and the patient dismissed. I have seen him since, at intervals, during the past three years, and there are no signs of recurrence of the disease.

*Case 2.*—Miss J., æt. 30, had considerable discharge from the right nostril, and had been treated for catarrh. The right side of her face was greatly swollen. Upon the affected side were found the second and third molars, the first bicuspid, and the canine in a healthy condition. The first molar and second bicuspid had been extracted for alveolar abscess three years previously. The swelling of the face had appeared twice before, for which she had been treated by her family physician. After lancing, a free discharge of pus followed and an opening was found into the antrum. After the usual treatment for five weeks, the discharge ceased, all the parts resumed their normal condition, and the opening in the antrum was allowed to close. In this case the suppuration was caused by one or both of the teeth previously extracted for alveolar abscess.

*Case 3.*—Mrs. P., æt. 45 years, who had been suffering for several years from intermittent fever, and had also been for some time troubled with a discharge of an offensive nature from the left nares which had been diagnosed as catarrhal, called to consult me about a first molar. Examination showed that all the teeth, from the canine including the third molar, had been removed, excepting the first molar. This was badly decayed, loose, and upon pressure, pus oozed from the socket. The tooth was extracted, disclosing a cavity into the antrum corresponding to the roots of the teeth. The extraction was followed by a copious, purulent, offensive discharge. There was considerable necrosis present. After treatment for over two months without any perceptible improvement, the patient left the city for the summer, and was under treatment while absent. At the expiration of four months, she returned, yet without improvement. Upon a thorough examination, a septum of bone, about one-quarter of an inch in height was found rising from the floor of the antrum, dividing the cavity into two parts. By means of a chisel, this septum was removed and found to be composed of cancellous tissue.

After this operation, the case readily yielded to treatment, and a recovery resulted.

*Case 4.*—Mr. J., æt. 23 years. In this case, there was no nasal discharge, the orifice from the sinus being closed by inspissated mucus. He complained of great weight and pressure on the affected side, severe otalgia and deafness. The second bicuspid was missing, and the first molar having a large amalgam filling was pulpless. This tooth was extracted, leaving a large opening into the antrum. There was also considerable necrosis, which was removed, and the usual stimulating treatment pursued for about four weeks, when the discharge ceased, and all other abnormal symptoms disappeared, excepting the deafness.

Miss S., æt. 19 years, consulted me with regard to a large swelling of the right side of her face. Before examination, I supposed that she was suffering from alveolar abscess; but to my astonishment, upon examination, all her teeth were found in a healthy condition, and the arch appeared unbroken. This clearly did not indicate alveolar abscess, but rather a diseased antrum. As the teeth all seemed to be present, I inquired whether she had previously received a blow upon that side of her face, or whether she had not recently contracted a severe cold. Receiving a negative reply to these questions, I made a second examination, and found that the first bicuspid was missing. She positively assured me that none of her teeth had been extracted. As the swelling pointed to the palatine as well as the facial surface, I lanced both surfaces, and was enabled to pass a probe from the facial surface into and through the floor of the antrum. She was dismissed until the next day, when I made a careful exploration of the sinus by means of an excavator, and found in the floor of the antrum the missing tooth imbedded in the inner coat of the mucous membrane, its apex toward the alæ. After the swelling subsided, the tooth was dislodged by means of a hoe excavator, and removed by means of a long, narrow-beaded forcep. After four weeks' treatment, the case was cured.

During the past eight months, in addition to the cases in my own practice, I have operated upon fourteen cases of diseased antrum for a throat and nose specialist. Of these cases, none resulted from chronic rhinitis, none from hypertrophic rhinitis, one from dentigerous cyst, two from polypi and eleven from diseased teeth. This seems to me clearly to refute the assertions of the authorities previously mentioned—that suppuration of the antrum is generally due to causes other than diseased teeth.

DR. RICHARD VOLKMAN, the famous surgeon of Halle, died at that city on the 28th ult.

## REPORT ON INTUBATION OF THE LARYNX.

*Read in the Section of Diseases of Children, at the Fortieth Annual Meeting of the American Medical Association, June, 1883.*

BY F. E. WAXHAM, M.D.,

PROFESSOR LARYNGOLOGY AND RHINOLOGY COLLEGE PHYSICIANS AND SURGEONS, OF CHICAGO; PROFESSOR LARYNGOLOGY AND RHINOLOGY POST-GRADUATE SCHOOL, OF CHICAGO.

It is my pleasure, Mr. Chairman, to report that intubation is still growing in favor, and fulfilling the expectations of its advocates. At the last meeting of this Association, I reported 150 cases coming under my personal care, with forty-one recoveries or 27.33 per cent. During the past year I have operated sixty times, with twenty-eight recoveries or 46.66 per cent.; making a total of 210 cases with sixty-nine recoveries or 32.85 per cent. The operation performed as it is, as a last resort, when the patient has been given up to die and other measures have been tried in vain, a saving of one out of three is a most satisfactory result, and places the procedure in the front rank among the life-saving operations.

It will be observed that the percentage of recoveries during the last year has been much larger than before, amounting to nearly 50 per cent. An interesting question arises as to the cause of this greater success. Some have unkindly attributed it to unnecessary operations, operations performed early and upon those that might have recovered under judicious medical treatment. It is only necessary, to say in reply, that more than nine-tenths of these cases are in consultation with other physicians, and the operator has been called only as a last resort.

The operation is not performed early, but in many instances only after the patient has become moribund and unconscious. Early operations do not enter into the question of increased success as the operations during the past year have been performed under the same conditions and circumstances as before. The question of treatment and its influence upon the results is an interesting one, but the observations have been too few to be of any great importance in this direction.

Of the sixty cases coming under my care during the past year, nineteen were treated with the bichloride of mercury, both before and after the operation, with nine recoveries or 47.36 per cent. Twenty-eight cases were treated with this agent, after the operation only, with fourteen recoveries or 50.00 per cent. Thirteen did not receive the bichloride of mercury either before or after the operation, and there were five recoveries or 38.46 per cent.

The type of the disease prevailing during the past year has not been different from that in former years, and the cases have been of equal severity.

The success during the past year I attribute to two causes: Improved methods of feeding and

greater experience, and better judgment in the management of the cases.

During the past year the greatest advance that has been made, has been the discovery of the proper method of feeding. The greatest objection that has ever been raised to intubation has been on account of the difficulty of feeding.

The falling of fluids and semisolids into the trachea, and their entrance into the finer bronchi giving rise to broncho-pneumonia, I have no doubt has too frequently been the cause of death. The objection and the dangers have been overcome by the adoption of the inclined position with the head down, during feeding or when drinking. One year ago I presented to this section a set of tubes with artificial epiglottis. These tubes answered a useful purpose, and were a great improvement over the open tubes while feeding in the upright position, but in the inclined position they are unnecessary, as patients can swallow in this position without difficulty.

Another cause of the greater success during the past year, is to be found in the increased knowledge that comes with experience, and the more watchful care of patients. Many cases have been saved only by the most watchful attention, and by timely interference.

A frequent cause of death is detachment of membrane and sudden suffocation from obstruction below the tube. This danger has never been exaggerated, but too frequently ignored. To overcome this danger I have had the tubes constructed with less swelling in the centre that they may be easily expelled. If they are ejected every few hours, no harm is done providing the operator is within reach to replace them. In case of partial detachment of membrane, which will be indicated by a hoarse cough, we should not wait, but anticipate the danger by removing the tube. The expulsive cough following the removal of the tube almost invariably expels the membrane.

Nothing is more dangerous in these cases, than to introduce a large tube that fits tightly and which cannot be expelled, and then leave the patient in fancied security. The record of my cases for the past year is as follows:

Age.	Cases.	Recoveries.	Per cent.
Under 2 years . . . . .	11	3	27.27
Between 2 and 3 . . . . .	8	2	25.00
" 3 and 4 . . . . .	9	4	44.44
" 4 and 5 . . . . .	17	8	47.05
" 5 and 6 . . . . .	4	3	75.00
" 6 and 7 . . . . .	3	3	100.00
" 7 and 8 . . . . .	5	4	80.00
" 8 and 9 . . . . .	2	1	50.00
One 12 . . . . .	1	0	00.00
	60	28	46.66

*Remarks.*—The youngest child operated upon was 6 months old. Those under 2 years that recovered were 15, 18 and 18 months, respectively. Every case, with one exception, was characterized by membrane formation. In the exceptional

case the stenosis of the larynx was complicated with a severe form of measles, and the patient died.

240 Wabash avenue.

DR. GEO. W. GAY, of Boston, said that the statistics of the Boston City Hospital were slightly in favor of tracheotomy, but intubation is more frequently done, being, on the whole, easier to perform. Of 327 tracheotomies 95, or 29 per cent., recovered; while of 223 intubations 47, or 21 per cent., recovered. In some cases, however, it was impossible to introduce the tube into the larynx. To perform intubation requires as much assistance as it does to make a tracheotomy, and there is as much danger of death on the operator's hands as there is during tracheotomy. In 310 cases of tracheotomy 10 had died from ether, shock, prostration or hæmorrhage; in intubation an equal number of cases died from strangulation or shock. Even if deposited with the utmost care, there was a moment of strangulation in every case. If this did not immediately pass off, the tube should be removed, and the membrane which causes the obstruction will be coughed out. It is dangerous to persistently try to force in a tube that always causes strangulation. When stenosis is not relieved by the intubation tube, when swallowing is impossible, or when the tube is constantly coughed up, tracheotomy is indicated. In 32 cases in which tracheotomy was done, after intubation had failed to give relief, 3 had recovered. There is no fixed treatment for croup, aside from the operation. He had used bichloride of mercury faithfully for two years. At one time he thought he saw benefit from it, but now he said that the facts do not warrant any conclusion. Feeding after either operation is most important; after intubation it should be done with the child lying on the side or on the back, with the head well down. There is no pathological evidence that the inspiration of food causes death. It is well known how the tracheal canula blocks up after tracheotomy. After intubation it does not. The trachea may fill up below the tube, but the tube remains clear. Outside the hospital Dr. Gay performs intubation among poor people who cannot properly care for a child after tracheotomy. He saw the child as often as he could. A certain number will always be lost from inability to find the operator when the tube becomes blocked, or when it is coughed out. In his judgment intubation is the better operation in ordinary cases.

DR. DENISON, of Colorado, said that from 60 to 70 per cent. of the deaths after intubation were the result of pulmonary complications. He had operated upon 25 cases, with 7 recoveries. Nine of the deaths were due to œdema of the lungs. In Colorado, on account of the rarefaction of the air, breathing is difficult, and little children were

very seriously affected by it. In one of his cases he noted that the pulse was very weak during inspiration, and stronger during expiration. The blood could not get out of the thorax during the labored inspiration, and this greatly interfered with the heart's action. He operated, and recovery resulted.

DR. E. F. BRUSH said that he had written the first article on intubation. He found Dr. O'Dwyer patiently working in his laboratory, perfecting the operation and apparatus, and was given permission to publish the results of Dr. O'Dwyer's work. He had gone enthusiastically into the use of intubation, but his results so far had not been favorable. He had performed 23 intubations, with but one recovery. One was an adult, who lived twelve hours after the operation. Experience leads him to agree with Dr. Gay as to the necessity of great care in the introduction of the tube. When called as a consultant it was necessary for the physician to carefully examine the case. It was useless to operate for pulmonary cedema, which might be mistaken for croup. He doubted the entrance of food into the lungs, and said he thought it was the great irritation set up by the cough that brought on the pneumonia when it was not the result of extension of the throat disease.

DR. J. A. LARRABEE'S experience was confined to tracheotomy. From the reports up to the present time the honors were about even between the two operations. Intubation was credited with being easier than tracheotomy, but this arose from different personal experiences. Some men acquired a delicacy of technique, like that of Tait in ovariectomy, or Waxham in intubation, which few can possess. To him intubation was the more difficult operation. It was more popular among the people, because it appeared to be a less formidable operation. No distinction is usually made by operators between croup and diphtheria, but he believes that such a distinction should be made. Membranous croup is a local disease, an exudation without sepsis; diphtheria is a systemic infection. In croup we operate and cure; in diphtheria, operation relieves but one symptom, and there is still the systemic disease to fight. Tracheotomy gives better results, because it does not interfere with medication and the administration of food. In infants under 2 years of age and in croup, intubation held the first place; for other cases tracheotomy was preferable. To prevent blocking up of the tubes he used a sponge saturated with warm water placed over the opening of the canula; also stemming of the tube. He was in the habit of pouring into the trachea a drachm of a solution containing chlorinated soda, and found it of great benefit.

## THE CLINIC.

### THE TREATMENT OF WOUNDS INVOLVING NERVES, TENDONS, AND MUSCLES.

*A Clinical Lecture Delivered in the Albany Hospital, Oct. 26, 1889.*

BY ALBERT VANDERVEER, M.D., PH.D.

PROFESSOR OF DIDACTIC, ABDOMINAL AND CLINICAL SURGERY,  
ALBANY MEDICAL COLLEGE.

[Reported for THE JOURNAL.]

*Gentlemen:* Permit me to call your attention this morning, in a practical manner, to the management of incised or lacerated wounds involving important nerves, tendons, and muscles. To come directly to our subject we shall present to you a patient, Mr. J. G., aged 22, single, native of the U. S., and by occupation a cigarmaker. He presented himself and was admitted to the hospital two days ago, with the following history: Two days prior to his admission he became involved in a saloon brawl and was struck by a beer glass which broke and inflicted a lacerated wound of the forearm. Hæmorrhage was very free and evidently arterial in character. A physician was called who applied a compress and firm bandage, which was allowed to remain until he applied for treatment at the hospital.

Upon examination at that time the hand was dark colored, much swollen and cold, owing to the compression of the bandage. The dressing was immediately removed, the wound washed, and a moist antiseptic dressing applied, together with moist heat. The first thing necessary was to restore circulation in the constricted parts, in which we have been fortunate. We will now remove the dressing and proceed to an examination of the present condition of the arm. You will observe that the wound is located about two inches above the wrist, beginning at the ulnar border and extending irregularly across the arm for an inch and a half. Its borders are elevated and irritable in appearance. There is an escape of bloodstained serum from the wound. The whole arm is yet swollen, and the circulation is feeble. When requested to flex the fingers the patient is unable to move the little, or ring finger, nor is he able to bring the thumb in apposition with index finger. He cannot flex the wrist to the ulnar side or move the fingers latterly. With the needle an area of anæsthesia is found along the ulnar border of the hand and involving the little and lateral half of the ring finger. The area of anæsthesia does not approach the borders of the wound. Upon closer examination portions of divided muscle and tendon appear in the wound. The pulsation in the ulnar artery is absent at the wrist.

Now what has happened? From the paralysis, both motor and sensory, we know that the ulnar nerve has been divided, or at least its func-

tion destroyed. The free hemorrhage, embarrassed circulation, and the location of the wound, all indicate a wound of the ulnar artery. The presence of muscle and divided tendon in the wound tells us of the damage done to the great flexors of the fingers. Here then we have a divided artery, nerve and tendons which have been under treatment for four days. Shall we continue our present mode of treatment? Shall we adopt a new method? The wound has already improved in appearance. The patient has no material rise in temperature. His general condition is good. But what are the consequences? This patient may have a secondary hæmorrhage at any moment. The wound, if not already infected, is exceedingly liable to become so, and suppuration threatens.

Again, the occupation of the young man requires both hands for him to gain a livelihood, and we can hope for no restoration of function in the severed muscles and tendons, or in the severed nerve. We have ahead of us cutaneous ulceration, causalgia, œdema, and muscular atrophy as tropic changes following division of nerves. Beside there is likely to follow the division of the ulnar nerve, that characteristic distortion, *main en griffe*, or claw hand. Manifestly much more is to be desired, and I believe can be promised, by an immediate operation, to which the patient has consented.

While the house surgeon is etherizing the patient we will recall to your minds the results obtained in similar cases treated by immediate suture in this clinic. First, the case of the carpenter who injured his hand in a planer. He had several incised wounds, compound and comminuted fractures of the outer metacarpals, division of the extensor tendons, and wounds of the palmar arch. Under ether we are able to control the hæmorrhage, to cleanse the wound by warm mercuric chloride (1-2000,) to remove the detached fragments of bone, to suture the tendons, and close and drain the wound. By careful antiseptic and fixed dressing we were able to give him a useful hand, with considerable power for extension.

The case of the colored man, wounded at the wrist by a broken pane of glass, opening the joint and dividing tendons. Cleansing and tendon suture with a most happy result.

The case of the child wounded by falling on a broken bottle, dividing the sciatic nerve in the thigh, high up. Treatment neglected for a year, when the cicatrix was divided and an unsuccessful effort made to find divided nerve ends and suture them.

The case of the young man who received a wound of the fore-arm, dividing tendons, arteries and nerves, and was treated without tendon or nerve suture. All these cases and the subsequent condition of the patients will be fresh in your minds.

As the patient is now ready we will proceed to the operation, beginning with an incision extending from the wound upward along the ulna two inches. A large blood clot is uncovered and turned out from between the layers of muscle. Hæmorrhage commences from the divided artery, which is immediately ligated at both ends. The cavity is thoroughly flushed out with warm mercuric chloride solution (1-2000), bleeding points ligated. The extensor tendons of the ring and little finger are found divided and are sutured by fine Chinese silk. Lastly, the divided ulnar nerve is caught up and carefully sutured in a similar manner. The wound is again irrigated with mercuric-chloride solution (1-2000), and closed by interrupted catgut sutures, a small drain being necessary in this neglected wound. Over all an antiseptic dressing of iodoform gauze and Gamgee pads. The arm is now placed in a posterior splint, with the hand well flexed and protected. This wound will undoubtedly heal kindly. Splint should be removed at the end of two weeks, and gentle passive movements commenced to prevent adhesion of tendons. It will be some time before the restoration of the function of the ulnar nerve. In this case we have from experience a reasonable hope for a favorable result.

Finally, gentlemen, I hope you will pardon me for going so much into the details, but I am convinced that if you will faithfully employ the method which you have seen to-day, in the immediate treatment of similar injuries, you will be amply repaid in success for your time and kindly attention.

November 4 and 9 the wound was re-dressed. No suppuration, parts healing rapidly. On the latter date patient could flex all his fingers slightly, but not encouraged to do so. Sensation was returning rapidly to parts supplied by the ulnar nerve.

## MEDICAL PROGRESS.

AN EPIDEMIC OF ULCERATIVE VACCINIA.—At a recent meeting of the *Académie de Médecine*, M. HERVIEUX reported the results of his investigations, relative to the appearance of ulcerative vaccinia among the school children of Motteaux Bois. Of thirty-eight children vaccinated thirty-seven presented the abnormal symptoms observed; these symptoms as they appeared on the thirteenth day after vaccination, consisted of intense inflammatory action, abundant suppuration, lymphangitis, œdema, fever and delirium. The period of incubation was eight, ten and twelve days. Six weeks after vaccination, nearly all of the children had entirely recovered. The virus was obtained from a boy 9 years of age, who presented an entirely healthy appearance with the

exception of lymphatic enlargements affecting the axillary, submaxillary and cervical glands. The boy's parents appeared healthy, but refused to submit to close inspection. A diagnosis of syphilitic infection was first made by the physicians who examined the cases, but this was subsequently changed because of the shortness of the period of incubation.

**PHYSIOLOGICAL ACTION OF THALLINE AND ITS CONTRAINDICATIONS.**—As the result of his experiments in the use of thalline M. ALBERT ROBIN formulates the following conclusions:

1. Thalline is a poison to the blood globules, the nervous system, and in general to tissues rich in sulphur and phosphorus.

2. Its antiseptic action within the organs of the body is insignificant and transitory.

As a corollary of its physiological action the following conclusions may be drawn:

1. Inasmuch as the antipyretic properties of thalline are united to its toxic effects upon the nervous system and upon the red globules of the blood, this remedy is a false and dangerous antipyretic which should be proscribed in the treatment of fevers.

2. Its power of retarding the elimination of uric acid renders it unfit for use in the uricæmic affections, and consequently in the greater number of cases of arthritis and nephritis.

3. Its prolonged employment tends to produce anæmia and to provoke in time more or less marked nervous disturbances.

4. The study of the effects of thalline points to the entire contraindication of the remedy.—*Le Bulletin Méd.*

**STERILIZATION OF MILK FOR INFANTS.**—DR. J. EISENBERG recommends the following plan for the sterilization of milk for nursing children: To prevent infection by the lactic ferment or by other microbes the milk should be suitably diluted with sugar water and then poured into bottles of convenient size. The bottles are then stoppered with cotton placed upon a wire tray and plunged into boiling water where they remain for 30 or 40 minutes until sterilization is complete. The contents of the bottles will remain free from alteration for many days. When it is desired to use the milk the cotton plug is withdrawn from one of the bottles and the nipple immediately adjusted.—*Wien. Klin. Woch.*

**A CONTRIBUTION TO THE PHYSICAL DIAGNOSIS OF THE INTERNAL ORGANS.**—RIESS (*Central. für Klin. Med.*) contributes the results of experiments in the diagnosis of internal organs.

**Percussion of the Kidneys:**—Riess directs attention to the percussion of the kidneys which he thinks deserves more attention than it has received hitherto inasmuch as it enables us to obtain the principal dimensions of the normal

kidneys. In 30 male individuals he was able by means of strong percussion to outline the kidneys on both sides; their distances from the median line varied from  $7\frac{1}{4}$ –11 cm. on the right side and from 7–10 cm. on the left side. In four cases the inferior borders on both sides could not be definitely determined; in a fifth case there was the same difficulty—on the left side alone. The average distance from the crest of the ileum was 2 cm. on the right and 2.5 cm. on the left side. In pathological conditions kidney percussion is especially important as a means of deciding whether the kidney is in its proper location; in the majority of such cases percussion leaves no doubts. Kidney percussion is also important in determining the presence and size of the enlarged organ.

**The So-called Metamorphic Respiratory Sound.**—RIESS is of the impression that this so-called symptom is by no means of rare occurrence. With the exception of a single case it was always found in connection with cavities; generally several large bronchi were found opening into a cavity. Riess believes with Seitz that this sound is a stenosis sound and explains it in this way: at the commencement of inspiration only one of the bronchi opens, this bronchus is small and in comparison with the other bronchi and the cavity itself it represents a narrowed canal; through a definite increase in the negative pressure established in the interior of the lung by inspiration, one or more of the other bronchi expand, the entering air is divided into several streams and the stenosis disappears.

**TRANSMISSION OF DISEASE BY DENTISTS AND HAIR DRESSERS.**—A discussion has recently taken place in Paris relative to the possibility of certain diseases through the agency of dentists and hair dressers. The discussion arose in connection with a report made by Dr. Lancereaux before the Council of Hygiene in the course of which he quoted an American dentist, Dr. Cochran, upon the transmissibility of pulmonary phthisis by means of dental instruments.

Dr. Dujardin-Beaumetz said that he did not believe that such a transmission had been demonstrated.

In his conclusions Dr. Lancereaux requests that he be advised of the danger incurred by their patrons in the use of instruments used upon numerous individuals and that dentists and even physicians be invited to carefully disinfect their instruments whenever used. After a long debate in which the difficulty of carrying out such measures was discussed the following provision of Dr. Lancereaux's report was adopted—viz.: that in every school where there are boarders each pupil shall have his own comb and brush which shall be kept for his individual use.—*Le Bul. SATURDAY, DECEMBER 21, 1889.

TO LIMIT THE CASTRATION OF WOMEN.

DR. C. TRUESDALE<sup>1</sup>, of Rock Island, in commenting on DR. MILLER'S<sup>2</sup> "Laparotomy Record," writes: "My first impression after reading said 'record' was that it was designed as a travesty on the frequency and recklessness with which the operations detailed in the report have been performed during the past five years; but on a more close examination I am convinced that the author intended it to be accepted as a correct report of what he actually did, and that it would be considered by the profession generally as a very brilliant feat of gynecological surgery. Assuming such to be the case, I am reluctantly constrained to say the report, as a whole and in detail, is simply astounding and to me incomprehensible. Forty-two women spayed, unsexed, mutilated in one year in a small out-of-the-way town in West Virginia!"

In the record, thus forcibly referred to by Dr. Truesdale, Dr. Miller does not enlighten us to a sufficient degree on the conditions and indications under which his operations were performed, so that we do not feel justified in entering into a detailed criticism of his "Year's Work in Laparotomy." Yet, in passing, we must confess our hearty sympathy with Dr. Truesdale in his indignant protest against what appears to be an unparalleled example of recklessness in abdominal

surgery. Dr. Miller's boldness is not lessened by the fact that his so-called report is merely a list of alleged successful abdominal sections. It is of little scientific value, inasmuch as the anatomical material has not been utilized, and because the ultimate results of the operations have not been stated. We allude to Dr. Miller's record merely as a text. Recklessness in the performance of TAIT'S operation is well-nigh universal, and it is high time to consider some effective method of limiting this pernicious activity. Within a very recent period three typical instances of the removal of the uterine appendages in the absence of a sufficient indication have come under our own personal observation, which we beg to note in the further illustration of the awful abuse of a valuable operative procedure. In the first case a young woman was supposed to be afflicted with a symmetrical mural fibroid about the size of a fetal head at term. The ovaries and tubes were promptly removed, but the uterine tumor continued to grow rapidly until, at the expiration of six months, the patient gave birth to a finely developed boy. While this case settles the question of ovarian influence in the determination of labor, and, therefore, is of considerable scientific importance, its history will never receive a more permanent record than the present fugitive notice.

Our second case is that of a wife in excellent health who had given birth to a child every two years for a decade. Fearing further increase in the family she consulted a prominent surgeon on the score of ovarian pain, in the absence of any demonstrable anatomical change. Tait's operation was done, and now both the surgeon and the woman are happy—the one over a successful laparotomy, and the other on her freedom from child-bearing. Of course the woman lied, but this fact does not palliate the surgeon's criminal stupidity in diagnosis, nor his unwarrantable haste in operation.

The third case presents an example of the transcendental casuistry by which a man of average candor and honesty may bring himself around to the commission of an atrocious crime. A young, highly educated woman, of a rather nervous temperament, is happily married for the space of three or four years. Eighteen months after marriage she becomes the mother of a healthy child; one and one-half years later a second in-

<sup>1</sup> Am. Journ. of Obstet., October, 1889, p. 1,045.

<sup>2</sup> "A Year's Record of Seventy-five Successful Cases of Abdominal Section," B. Curtis Miller, M.D., Charleston, W. Va. Am. Journ. of Obstet., July, 1889.

fant comes into the world. About the time of the birth of the second child the husband acquires the morphine and cocaine habit. The wife, passionately devoted to him, is at once thrown into a nervous, hysterical state, and her importunate solicitude irritates her husband into still greater excesses. Upon the occasion of one of these uncommonly prolonged debauches the wife takes a dose of chloral with suicidal intent. At last the husband, who is not unfamiliar with medicine, conceives the idea that his wife's tubes and ovaries are at the bottom of the domestic troubles, and he seeks professional advice. Bimanual exploration fails to reveal any anomaly whatever of the pelvic viscera. Moreover, the history of the two recent, normal pregnancies at short intervals is brought forward in evidence of the physiological condition of the woman's genital system. Finally the wife herself asserts, in the presence of witnesses, that her nervous condition is due solely to her anxiety about her husband's unfortunate habit. By more than one physician the husband is urged to reform himself, as the surest means of curing his wife. But all to no purpose, for the man, in his wretched, irresponsible state of mind from the use of narcotics, finds a legally qualified practitioner that immediately relieves the wife of her perfectly normal tubes and ovaries. The woman has recovered from the operation, but her state of mind is unchanged, and it must remain unchanged, so long as the original cause of the mental disturbance is operative. As before remarked, this case is of especial interest to the student of casuistry, to whom may be left the analysis of the peculiar mental process by which this practitioner brought himself to the point of operating.

Only a few months ago a case was unblushingly reported in the *Boston Medical and Surgical Journal*, in which normal tube and ovaries were cut out of the body of a young unmarried woman under the indication of masturbation!

It is needless to multiply examples of this prostitution of surgery. Let us turn to the more hopeful topic of prevention. To begin, it may be said that the profession itself is amply able to arrest the further progress of this horrible heresy. There is no occasion to institute a crusade, to invoke the power of the press, as HORACE GREELEY did against bleeding; neither is the necessity apparent of calling upon the "Society for the Pro-

tection of Women," nor upon the local and national Legislatures.

The method of limiting the castration of women that we propose is simple, and we believe it will prove efficient. Make it an essential condition to the performance of Tait's or of Battey's operation, in all cases presenting no gross tangible lesion of the organs, that there shall be held a consultation of at least three responsible physicians.

We believe that this plan would secure accuracy of diagnosis. Now, it is a fact that the expert spayer of women is not always equally adroit in the recognition of anatomical changes nor in the interpretation of morbid processes. And the best of men often mistake the nerve-counterfeits of uterine and ovarian disease. WILLIAM GOODELL<sup>3</sup> has raised a voice of warning upon this topic, which merits the serious attention, that it will doubtless receive. Then, too, when this condition is fulfilled, we are of the opinion that slight and harmless enlargements of the ovaries will be regarded less frequently as morbid phenomena under such euphonious titles as "ovaritis," "cirrhosis" and "cystic degeneration." This statement does not deny the existence nor the moment of such pathological alterations, but it does imply that insignificant changes in the ovarian stroma, in the one case, and in the ovisacs, in the other, are often misnamed, and invested with a purely imaginary dignity in pathology.

BENJAMIN RUSH did not like consultations. He said they were the ineffectual result of neutralized opinion. But this "neutralized opinion" and its consequent delay in action represents exactly the end, we hold distinctly in view.

For a long period, the formal assent of three qualified practitioners has been insisted upon as a necessary condition to the artificial induction of abortion, and experience has demonstrated the wisdom and efficiency of the injunction. In former times, this operation was abused much in the same manner and degree that the castration of women is now prostituted. But under the influence of this condition—the primary factor, as we think,—clear and distinct indications have been formulated, which determine the action of all physicians, that respect their art and reputations.

It goes without saying that the consultants

<sup>3</sup> "The Abuse of Uterine Treatment Through Mistaken Diagnosis." *The Medical News*, December 7, 1889, p. 621.

must be responsible men, the peers of the would-be operator, and not subordinates, that might naturally be expected to echo the opinions of their chief.

#### LOCAL MEDICAL SOCIETIES.

The need of higher standards of medical education in the United States is universally conceded. Indeed the persistent efforts of many of our leading medical colleges and an earnest advocacy on the part of our prominent medical journals have rendered much valuable service in this direction. Some of our schools are now making such requirements as would remedy the evils of illiteracy were their standards to be generally accepted.

But it is idle to presume that the profession can be purged of incompetency while any medical school, if it shall so elect, may barter its diplomacy as merchandise, and be alone responsible for the proficiency of its graduates. If short terms of study are advertised, if low fees only are required, and if a surety of graduation may be anticipated, it will not be singular if such schools receive a liberal patronage, and the medical profession continue to suffer from the influx of such illiteracy.

While the great majority of our able physicians and the best of our medical colleges may most earnestly desire it otherwise, yet the fact remains that no appeal to reason—to honor—or to the interest of humanity will suffice to remedy the evil and compel a certain class of colleges to the needed reform. Only compulsory legislation will meet their cases and let us be thankful and take courage in the fact that legislation can do it.

It is not within the province of the general government to deal with this matter *but* it is competent for the several States so to do.

This vested right is not only conceded, but already many of the States are acting in recognition of that right and in several of them the thoroughness of legislation leaves little more to be desired.

Medical legislation in the several States must of necessity be largely influenced by an intelligent expression on the part of the profession as to what the general good requires. It is due to the several legislative bodies that the needs of their State, so far as regards medical legislation, be clearly and wisely set forth. The leading medi-

cal men of a State more than any others are competent to indicate what such legislation should be.

The expressions of their judgments should be clear, concise and just, and coming to an intelligent body of legislators such an expression, from a united profession, will largely influence its action.

In the attainment of such results it is essential that the entire local societies of the several States be ably represented in their State organizations. It is here that any conflicting views may be reconciled. It is here that the influence of the medical men of a State may be best harmonized and unified. It is in our State Medical Societies that the appropriate measures can be devised by which to secure needed legislation, and it is through the agency of its members located in the various sections of each State, that the individual members of the State Legislatures can be reached and their favorable action be secured. If, then, the future advancement of medicine in America shall be dependent in large measure upon State legislation, and if the several legislative bodies are to be successfully influenced by concerted action on the part of the medical profession, and if that concerted action can be secured through the harmonious working of State Medical Societies, does it not follow that with them more than with any other medical organizations rests the responsibility of securing to our country that immunity from ignorance, charlatanism and quackery to which as free and intelligent people they are entitled. Recognizing the failures of simple persuasion in the past, let us address ourselves to the only efficient remedy—that of appropriate State legislation.

#### EDITORIAL NOTES.

##### HOME.

THE NEW YORK SYSTEM OF CORONERS.—The New York Society of Medical Jurisprudence has had under discussion the abuses of the system of coroners and a committee has been empowered to draft a law which, if enacted by the next session of the Legislature, will abolish that antiquated system. In its place, the Society desires to see inaugurated a system of medical examiners resembling that which has succeeded so admirably in the State of Massachusetts. It is stated as an actuality that during a recent inquest, the Coroner asked a witness if the *rigor mortis* was a sure sign of death, and again, if there was any way of determining if a post-mortem had been

performed before death. The fierce light that beats upon the office of coroner has of late revealed so little that is creditable to it, that it cannot long perpetuate itself in an intelligent and observant community. The present Board of Coroners find the proposed legislation highly objectionable and retort upon the society, above named, that its real object is to manufacture new officers for some of its medical associates.

**MEMORIAL TO THE LATE DR. CABELL.**—A memorial window is to be erected in the new chapel at the University of Virginia in memory of the late Dr. James L. Cabell.

It is stated that another Woman's Medical College is to be started in Cincinnati.

**THE WIDOW OF THE LATE DR. C. R. AGNEW** has been appointed by Mayor Grant a member of the Board of Education of New York.

**PHILADELPHIA MEDICO-LEGAL SOCIETY.**—At a recent meeting of this Society the following were elected officers: President, Dr. W. F. Waugh; First Vice-President, Dr. Martin; Second Vice-President, Dr. W. Buckby; Recording Secretary, Dr. Horace K. Reeger; Corresponding Secretary, Dr. T. H. McBride; Treasurer, Dr. G. M. D. Peltz; Board of Censors, Drs. Connor, Hazel and Stewart; Librarian, Dr. Nash.

**A PHYSICIAN TAKEN WITH PARALYSIS WHILE ACTING AS CHAIRMAN.**—Dr. J. P. Bancroft of Concord, N. H., was the presiding officer at a meeting of the New England Psychological Society, when he noticed a gradual loss of power creeping over his left side. He had the fortitude to remain in the discharge of his duties and put the motion to adjourn, although his fellow members were, at that very moment, assisting in maintaining his erect posture. *The Boston Medical and Surgical Journal* takes pleasure in reporting that Dr. Bancroft has not been seriously paralyzed, but has manifestly improved in muscular power since the time of the attack.

#### FOREIGN.

**MEDICAL PROGRESS IN CHINA.**—The Chinese government has determined to form medical bureaux for the army and navy, upon Occidental models; requests for information from the United States departments have been made in regard to hospital organization and ambulance service. A

foreigner will be made Surgeon-General, with an adequate staff of assistants who have been trained in the schools of the civilized world. A beginning will be made in northern China, by the building up of a medical college and several hospitals and dispensaries at a number of the military stations in that part of the kingdom. Native surgeons will be appointed to the fleet, chiefly from among young men who have been educated in this country, under the auspices of the Chinese Educational Mission. The importance of this step, in the way of medical reform, is very great, since it gives the stamp of official recognition, in departments of highest influence, to the modern systems of military and naval service, and sends into retirement the effete methods that have hitherto been honored.

**THE SOCIETY OF MUTUAL AUTOPSY AT PARIS** had for one of its members the late General Faidherbe. His will explicitly bequeathed his body, and especially his brain and skull, to the Laboratory of Anthropology to be utilized for the benefit of science. The carrying out of this behest has been opposed by the General's widow and heirs, on the ground that the "ravages of disease have rendered an examination undesirable," and it will probably be frustrated. Among the early members of this Society who have been true to their post-mortem obligations, were Dr. Paul Broca and Gambetta. When Gambetta's brain was dissected it showed a marked development of Broca's convolution, and since he was one of the most fluent men in his generation, he was thought to have furnished a happy confirmation of Broca's theory.

**THE INTERNATIONAL MEDICAL CONGRESS OF 1890.**—The Budget of the German Imperial Home Office allots 80,000 marks as a contribution to the expenses of the Tenth International Medical Congress, which is to meet in Berlin next year, and assigns the following reasons: "The considerable expenses which these congresses entail are, as is proved by experience, only partly covered by the contributions of the members, so that, on former occasions, especially at the last congresses in Copenhagen and Washington, considerable subsidies were granted by the respective governments from public funds for the defrayal of the expenses. It will not be possible for the empire to lag behind other States in this respect."

## TOPICS OF THE WEEK.

### A VOICE ON MEDICAL EDUCATION FROM CALIFORNIA.

It is well known that the medical schools of California have exacted a preliminary examination of their students, and three years of college study. But it is also true that the State Board of Examiners have recognized the diplomas from medical schools elsewhere that made no such requirements. At this late day this Board has determined that on and after April 1, 1891, it will refuse to recognize the diplomas from all medical colleges that do not exact from their students three years of college study. This is well, but the requisition of the same years ago, would have been still better.

The California medical colleges require a preliminary examination, why does not the State Board exact such an examination of the medical colleges whose diplomas it recognizes? The claim of the *Pacific Med. Journal* that this Board should exact from the colleges whose diplomas it recognizes at least as high a grade of preparation as that demanded by the California medical colleges, seems to us perfectly reasonable. We hope that it will continue to press the matter until the Board has done its duty to the colleges of its own State, and the medical profession everywhere. It is difficult to understand why this Board has not already done this scant justice to the cause of medical education. If there is any lack of doctors for the needs of the people of California, the colleges have adequate machinery to supply the demand.

Generally the medical colleges resist the line of progress, but in this State it seems that the colleges are ahead of the State Licensing Board.

Many are the discouragements of those who seek the uplifting of the medical profession to a higher grade of scholarship, general and special, but it would seem that no State Board should stand in the way of such advancement. In the case of the California Board we read the indication, from its requirement of three college years after next year, that in the near future it will still farther advance in the matter of preliminary education.

We venture to make a suggestion respecting the preliminary examination, viz.: that it shall require as evidence that any college has exacted a proper preliminary examination in any given case, a diploma of the degree of A. B., or a certificate signed by the President and Secretary of a standard literary college, showing that the holder of said certificate has actually passed the examination requisite for admission into the Freshman class of said college. This is an entirely feasible requirement, and would give confidence in the actual preliminary training of the applicants for admission to the medical colleges. The time has come to insist that all the applicants for entrance into the professions must pass first through the literary or scientific colleges. It should be the business of the professional schools to compel those desirous of admission to their doors, to show that they already possessed the proper training for the intelligent and profitable pursuit of the studies there taught.

There are indications that the time when this may be realized is approaching. But the friends of this progress

must not slack in their efforts to fulfil the conditions necessary to this end. California listens to the voice from Minnesota, Minnesota responds to the cry in Virginia, Virginia shows that she heard the speech from North Carolina, North Carolina proved that she had heard the voice from Illinois, from all these States Montana drew the inspiration that induced it to organize for the uplifting of the medical profession. These one by one listened to the individual and collective efforts by many earnest teachers of the better way echoing through the corridors of the past century. The conflict is between ignorance, greed, selfishness, vanity, and boodles on the one hand, and intelligence, unselfishness, manly integrity, and professional spirit on the other. The issue at the last none can doubt, but the speedy realization of this issue depends upon the vigorous and self-denying efforts of its advocates.—Correspondence, *American Lancet*.

### PROFESSOR NUSSBAUM ON RECOVERY AFTER WOUNDS AND OPERATIONS.

PROFESSOR NUSSBAUM has found that a very good prognosis of the healing of surgical wounds can be obtained by examining the secretion from the surface during the first two or three days. If this be sanguinolent, prognosis is more or less bad. Care must be taken not to confound any slight after-bleeding with true sanguinolent secretion. The prognosis is only bad where the secretion from the whole surface of the wound is tinged with blood. Thus, when a day after a litholapaxy has been performed the urine is quite free from a reddish tinge the prognosis is good, or if two or three days after the amputation of a breast when the dressing is changed there is no general sanguinolent stain on the latter, but only, may be, a few little blood clots here and there, it is most likely that the wound will heal satisfactorily. Again, if the secretion becomes free from blood on the fourth or fifth day, the prognosis, though not quite so satisfactory as if there had been none at all after a few hours, is still decidedly better than if it continues bloody up till the sixth or eighth day. In such a case the patient is sure, if he recovers at all, to be very slow about it. In phthisical persons and hard drinkers there is nearly always a great tendency to a prolonged secretion of sanguinolent matter after wounds, and sometimes the tinge remains throughout the healing process, which is in these cases very tedious. When the secretion on the first day is free from blood, it shows that the capillaries are closed, and therefore that the intracapillary pressure is normal. Again, it is evident that when the intracapillary pressure is low the endosmose and the exosmose between the vessels and the tissues cannot be taking place properly, and thus that the due healing of the wound cannot be expected to proceed as it ought.—*The Lancet*.

### MEDICINE AND THE ARTS.

Every now and again comes a cheerful reminder that the pursuit of medicine does not destroy artistic perceptions, even though it is currently held that devotion to any science tends to develop the "scientific frame of mind" until it is all-absorbing. Those who have had no

scientific training never seem to weary in denouncing the avidity for facts and the scepticism for theories with which they credit those whose habit of thought differs in many respects from their own. The medical profession in particular is selected for cheap satire. The interest of the dissecting-room and physiological laboratory and the watchful anxiety bestowed upon hospital patients are alike misunderstood by many who have never penetrated the inner life of a medical man. To those who know, however, there is a deal of human nature in the medical profession, and it seeks expression and distraction in many unsuspected directions. Painters, etchers and photographers abound in our ranks, while music not only claims many instrumentalists, but even the publication devoted to Wagner and all things Wagnerian is edited by a member of our profession. In such meditations upon harmony does Mr. W. Ashton Ellis find repose in the midst of the turmoil of conflict on behalf of the Members of the Royal College of Surgeons in their endeavor to obtain a restitution of their corporate rights. The current number of the *Meister*, with its article upon the Bayreuth Hush, seems pervaded by a sense of peace in striking contrast to the correspondence so ably conducted at the beginning of the year.—*The Lancet*.

#### PASTEURISM IN BRAZIL.

Statistics recently published by our Brazilian contemporary, the *Revista Medica de S. Paulo*, state that the first antirabic inoculation carried out in Brazil was performed at Rio de Janeiro on February 9, 1888. Between that date and August 14, 1889, 342 persons had presented themselves at the institute. Of these, 135 had been bitten by dogs quite free from disease, 14 had not been bitten at all, and 37 did not put in an appearance after the first visit. From the remaining 156 who underwent the treatment the director of the institute, Senor Ferreira dos Santos, eliminates 6 more, namely, 5 who, having been slightly bitten by dogs as to which there were not strong grounds of suspicion, did not complete the course, and one who, having been severely bitten on the head, died of hydrophobia during treatment. In this last case, however, the patient had failed to attend ten times in twenty-three days. Three children who were badly bitten by the same dog are still quite well, more than a year having now elapsed from the date of the injury. In 141 cases the bites were inflicted by dogs, in 15 by cats. The condition of the animal was ascertained in 19 cases by positive results following inoculation of its medulla, or by the disease declaring itself in animals bitten at the same time; in 67 by the animal showing unequivocal signs of the disease, and in 70 by its exhibiting "very suspicious" symptoms. Of the 150 cases in which the treatment was thoroughly carried out only one died—a mortality of 0.66 per cent.

#### THE TALE OF EYAM. A STORY OF THE PLAGUE IN DERBYSHIRE.

The village of Eyam in Derbyshire was desolated by the plague in 1666. For twelve months, from September, 1665, to the autumn of 1666, the ravages of the awful pest were so terrible that only one-sixth of the inhab-

itants were left to tell the story. The villagers solemnly agreed, at the time of "the visitation," that on no account would they pass beyond a boundary line drawn around the village. Food was brought to several points by those outside and placed upon the ground. In the middle of a field at the back of the village are seven stones to the memory of seven members of one family carried off on seven successive days. The author of the poem which tells the story of the pest says:

Long may these stones be left, sad proof to all  
Of how our brave men died in that past age.

The picture of utter helplessness in presence of such a calamity is painted by the author in vivid colors. In that age, under such terrible circumstances, a brave man had but to stand still and die; he knew nothing of the origin or the nature of his enemy. How could he fight "the foul and unsurpassed pestilence," of which he knew nothing but that its dart was certainly fatal? Let those who say that medicine has not kept pace with other branches of science read this piteous tale and compare our attitude now in presence of dire disease with that of the poor folk at Eyam, who built a wall round the spot on which they had but helplessly to perish. The author speaks of the pestilence and "its hellborn brood," and again of firebolts from "heaven's reeking nostrils." Such poetic phraseology aptly exemplifies the mental attitude of men who lived in the infancy of modern science, when in the plague (*plaga*—a blow) they saw the angry stroke of offended Deity, and recognized the "scourge" of God in what we know to be only the scourge of filth.—Review, *Brit. Med. Journ.*

#### NEW ITALIAN REVIEW ON HYGIENE.

A further indication of the progress which is being made in matters relating to public health and sanitary science in the kingdom of Italy is afforded by the promise of the issue next month of the first number of a Review on Hygiene, which will be compiled under the direction of Dr. Eugenio Fazio. The subjects to be dealt with are as follows: Biology, bacteriology, infection and sanitary police, the natural sciences as applied to public health, demography, statistics and sanitary engineering. We are glad to find that the Review will emanate from Naples, for the southern portion of the Italian peninsula stands, we fear, much in need of an educational movement in the direction of hygiene. For this reason, too, the Review has our good wishes.

#### POST-GRADUATE COURSES IN VIENNA.

The number of American and English physicians attending courses in Vienna has again increased this year. Over eighty fresh students arrived here last month from America and England. More than sixty courses on various branches of medicine are conducted here during the whole session. They last from four to six weeks. The courses on Laryngoscopy, Ear Diseases and Gynecology are especially well attended. It is hoped that the proposed Anglo-American Medical Association will soon be formed, as its by-laws will be approved by the Austrian Government within the next few days. Students can easily obtain information here as to the courses, a list of which is published every week by the *Vienna Weekly News*, and is posted on boards, etc., at the Medical Inquiry Office, IX, Maximiliansplatz, 13, and at the English Library, I, Landesgerichtsstrasse, 12.

## PRACTICAL NOTES.

### DISINFECTION IN CONTAGIOUS DISEASES AND EPIDEMICS.

The Council of Public Hygiene and Health of the Rhone has issued the following instructions relative to disinfection:

#### 1. PRECAUTIONS TO BE TAKEN BY THE ATTENDANTS UPON THE SICK.

Persons caring for the sick shall be provided with garments which must be changed, 1st. When leaving the house; 2nd. During meals; 3rd. When the attendants are obliged to come in contact with healthy persons in the house.

They must wash their hands frequently, especially before meals, with soap and large quantities of water, renewed several times.

#### 2. DISINFECTION OF UTENSILS USED BY THE SICK.

Cups, bowls, plates, spoons, etc. used by the sick, must be carefully cleaned with boiling water and they must not be used by other persons.

The remains of food left by the sick must not be eaten by healthy persons.

#### 3. DISINFECTION OF EXCREMENTITIOUS MATTERS, ETC.

Vomited matters and the dejecta must be immediately mixed with a glassful of an acidulated solution of sulphate of copper, (water 100 grm., sulphate of copper 2 grm., ordinary sulphuric acid 4 grm.) and then thrown into the water closet. The vessels which are used to receive these matters must be first rinsed and then immediately treated with first, another glassful of the acidulated solution of sulphate of copper and then with a large quantity of ordinary water.

In the country these matters must be buried, after disinfection, far from all water supplies for domestic uses.

If matters have been spread upon the floor they must be absorbed by sawdust, which must be immediately burned. The remainder must then be removed by a sponge or clout impregnated with carbolic acid, to be disposed of as hereinafter described.

If bedding, napkins or handkerchiefs have been soiled these articles must be immersed in a solution of carbolic acid, and treated as will presently be described.

#### 4. DISINFECTION OF LINEN DURING THE COURSE OF THE DISEASE.

Body linen, napkins, handkerchiefs and bedding must be disinfected in the house before being sent to the laundry. For this purpose whether soiled or not, when changed they must first be immersed for half a day at least in a tub filled with a two per-cent carbolic solution, they must then be lightly wrung out and placed in

boiling water for twenty minutes or half an hour they must then be put in the wash or sent to the laundry.

It is very important to remember that all discharges from the patient must not be permitted to dry upon the linen.

Treatment by the disinfecting oven is preferable to boiling when this is possible.

The carbolic acid solution thus employed must be turned into the water closet, and not into the sinks.

Linen and dressings of little value must be burned; otherwise they must be disinfected in the same manner as body linen.

#### 5. DISINFECTING OF CLOTHING, BEDDING, CARPETS AND HANGINGS AT THE END OF THE DISEASE.

The clothing of the sick, the bedding, (coverings, mattress, pillows,) and the carpet and curtains of the sick room must be enveloped in cloths moistened with water or a carbolized solution and then be conveyed to a disinfecting oven where they are subjected for twenty minutes to the action of steam without pressure.

These articles must not be returned to their places until the room has been disinfected.

Wearing apparel must also be treated in this manner even if it is to be given away or sold.

#### 6. DISINFECTION OF THE FURNITURE FOR THE SICK ROOM.

This procedure includes several steps which must always be taken in the following order:

1. Moisten the floor uniformly with water.

2. Carefully wipe the ceiling, the walls or the hangings with a cloth slightly dampened so as to remove the dust.

3. Furniture of small value, such as common chairs, etc., must be liberally treated with a sublimate solution (1-1000).

The inside of night chairs should always be so treated.

4. In the more important furniture such as beds and hair mattresses all the joints and crevices must be treated with the solution of sublimate as in the destruction of vermin; waxed and varnished surfaces must be wiped with a cloth impregnated with oil.

5. Upholstered chairs must be beaten and then rubbed with a brush dipped in the sublimate solution.

6. The floor of the chamber and the wainscoting and walls up to a height of 6 feet must be washed and cleaned with brushes and sponges dipped in the sublimate solution.

7. Not later than two hours afterwards a second liberal washing must be given with sponges dipped this time in an alkaline solution (water 100 grm., carbonate or crystals of commercial soda 10 grm.).

At the same time the less valuable furniture

which has previously been treated with the sublimate solution must now be well washed with the alkaline solution.

8. The excess of the solution must be mopped up, the room well ventilated so as to dry the walls and floor as quickly as possible.

The preceding measures ought to insure sufficient security.

In case, however, the rooms to be disinfected can be dispensed with for 48 hours it is well to complete the disinfection by fumigation with sulphurous acid.

For this purpose before drying the room an iron vessel is placed in the middle of the floor; into this is placed flowers of sulphur in the proportion of 15 to 20 grm. per cubic metre of the space to be disinfected. To avoid danger of fire the vessel containing the sulphur should be placed in a large receptacle containing 5 or 6 centimetres of water. The chimney is then stopped and strips of paper are pasted over all cracks where the vapor might escape. Metallic objects which can not be removed are covered with grease. Alcohol is then poured upon the sulphur and ignited. The door of the apartment is then closed and the crevices covered with strips of paper. Sulphurous acid gas is evolved and should be confined for 12 hours at least. The next day the room is well aired. It may be re-occupied as soon as the gas which generally provokes irritation of the eyes and throat is no longer noticed—this will generally be in about 24 hours after the windows have been opened.

Finally when possible it will be advisable to repaper or repaint the walls as the case may be. —*La Prov. Méd.*

## SOCIETY PROCEEDINGS.

### New York Academy of Medicine.

*Meeting of the Section of Obstetrics and Gynecology, November 27, 1880.*

This meeting was devoted to a discussion of the use of electricity in gynecological practice.

DR. A. D. ROCKWELL opened the discussion with a paper on

#### GENERAL OBSERVATIONS ON THE USE OF ELECTRICITY IN GYNECOLOGY,

which consisted of a comprehensive survey of the whole field, with special reference to the rationale of the effects of electrical treatment. In speaking of the faradic current he said that its action on the muscular fibre of the uterus was analogous to that of ergot, although manifestly more prompt and energetic, especially under the influence of the positive pole. By this action a veritable interstitial massage was obtained, and it was potent in overcoming the primary inertia of the uterus

and in preventing an arrest of retrograde metamorphosis, through which comes subinvolution and its inevitable and persistent sequelæ. When the processes that went to make up the graver and more chronic diseases of the uterine parenchyma and its lining membrane has continued a long time, he said, the galvano-chemical cauterizing effects of the galvanic current are called for in the treatment. By the interpolar influence of the current we correct a languid nutrition and hasten the absorption of exudation. The positive pole has an action peculiar to itself, which is directly hæmostatic, and it is therefore indicated in all hæmorrhagic conditions, as well as when there exists an excess of the natural secretion. On the other hand, the absorption process is undoubtedly more active under the influence of the negative pole, and is especially indicated in indurated chronic metritis and for the resolution of fibroids. That the galvanic current often completely dissipates fibroid tumors of the uterus few would affirm, but the symptoms can be relieved, to a greater or less extent, by electrolysis, and sometimes so completely as to lead to the belief, so far as the patient is concerned, that the tumor has entirely disappeared.

Dr. Rockwell is a believer in the great utility of the galvanic current in the absorption of the thickenings and infiltrations resulting from inflammation of the pelvic cellular tissue, and in dissipating uterine and ovarian pain. He related a case in which the patient had suffered intensely from dysmenorrhœa for six or seven years, and had finally submitted to extirpation of the ovaries for its relief. The flow had gradually diminished, but the pains had only increased in severity after the operation. Under internal applications of the galvanic current, however, the paroxysms yielded rapidly, and in a few months recovery was complete.

Next came papers on *The Treatment of Certain Pelvic Tumors by Galvano-Puncture and Drainage by the Vagina and Intra-Uterine Galvanization*, and on *The Galvanic Treatment of Uterine Fibromata*, by DR. A. A. GOELET and DR. E. L. H. MCGINNIS. Both these gentlemen have visited Apostoli in Paris and carefully studied his methods. One of the most interesting portions of Dr. Goelet's paper was that in which he spoke of the electrical treatment of hydrosalpinx and pyosalpinx. In hydrosalpinx he uses the negative pole through a canula, with not more than 50 milliamperes for five minutes at a time. In pyosalpinx the cavity should be washed out with an antiseptic solution and the positive pole be employed, as being less irritating, and because it is believed to be more antiseptic. He stated that the cauterization of the track of the puncture by the current shut it off from the surrounding tissues and rendered the absorption of septic material through that channel impossible; and if a dressing of iodo-

form gauze were kept constantly renewed in the vagina there was nothing to be apprehended from that source. Resolution in the diseased tube was promoted by the influence of the current, and was still further favored subsequently by mild positive galvanization of the endometrium. He limits this treatment by aspiration to such tubes as are close to the vaginal wall, and when fluctuation may be distinctly felt. This treatment was suggested to Dr. Goelet by observation of three cases of radical cure of hydrocele accomplished by the method. He has also successfully treated in the same way small cysts close to the vaginal wall, though fibro-cysts are sometimes more obstinate in yielding. A considerable portion of the paper was naturally devoted to the treatment of fibroids, and near its conclusion he quoted the following opinion of Thomas Keith in regard to electrical treatment and hysterectomy: "Apostoli's method, though slow and requiring much patience, tenderness of manipulation and thought, is still sure in its results. . . . Hysterectomy, which is performed every day for a complaint that rarely of itself shortens life, kills every fourth or fifth woman that is subjected to it. This mortality must cease. It is not a question of surgery; it is a question of humanity. Every time that any disease can be cured without resorting to a bloody and dangerous operation, such as hysterectomy, progress is made in our art and there is gain to humanity, while surgery is the better for being purged of a deadly operation."

DR. A. H. BUCKMASTER, of Brooklyn, read some

#### NOTES ON THE TREATMENT OF FIBROMATA BY ELECTRICITY.

He gave an account of a series of original experiments made for the purpose of testing the direct effect of electricity on various tissues. He used the exposed heart of a living dog for the passing of the current, as presenting a tissue as nearly analogous as possible to myo-fibroma.

DR. A. LAPHORN SMITH, of Montreal, read a paper on

#### BIPOLAR FARADIZATION IN GYNECOLOGY,

in which he spoke highly of the use of the coarse wire coil in post-partum hæmorrhage, in subinvolution due to the defective contraction of the uterus, in deformity and displacement of the uterus due to relaxation of its own walls or of the muscles which hold it in the center of the pelvis, etc. He mentioned the following as advantages of the bipolar method: 1. It is less painful than the old method. 2. It is easier to apply. 3. It allows a much stronger current to be tolerated. 4. It is, consequently, more effective, because the higher the intensity of the dose, the more marked the effects.

There are three kinds of cases in which Dr. Smith has found the fine wire bipolar faradization

remarkably beneficial, viz: 1. Ovarian pain where no organic disease can be found. 2. Abdominal pain due to hysteria. 3. In women about the age of 30, who, though fleshy and apparently well supplied with blood, do not menstruate at all, or only very slightly, and are apt to become hypochondriacs. 4. In vaginismus, which he considers to be due to hyperæsthesia of the nerve terminals about the entrance of the vagina, and is really a form of vaginismus.

DR. P. F. MUNDÉ, in the discussion which followed, said he could speak most decidedly in favor of electricity in gynecology, and that he had seen more benefit derived from galvanism than faradism. He had also found that mild currents employed for a long time were, as a rule, more efficacious than strong currents used for a short time. He did not regard the milliampère metre as of much practical value. When using galvanism for the relief of pain he thought the sensations of the patient were a sufficient guide as to the strength of the current employed. When, however, the current was used in patients under an anæsthetic or for the galvano-puncture, he considered the metre necessary.

He said that he had employed electricity once with success in extra-uterine pregnancy, but as the shock was so severe as nearly to kill the patient, he was at present somewhat undecided as to whether this was the best plan of treatment or not. In pyosalpinx and pelvic abscess laparotomy and drainage are, in his opinion, certainly preferable to galvano-puncture. Out of 123 cases of uterine fibroids coming under his observation only eight seemed to him to require Apostoli's method, while four others called for galvano-puncture through the vagina. The latter appeared to him to be the ideal treatment for the cure of this class of tumors, and in all four of the cases in which he resorted to it the growth entirely disappeared and the patients were absolutely cured. In regard to Apostoli's method, with intra-uterine galvanism and the clay electrode on the abdomen; while it was unquestionably true that it relieved pain and checked hæmorrhage and that patients generally felt better for its use, in not a single one of the eight in which he had employed it had the tumor been much reduced in size.

DR. FRANKLIN H. MARTIN, of Chicago, exhibited an admirable

#### NEW PORTABLE BATTERY,

which he said was the outcome of a series of experiments made with the end in view of bringing forth a small portable battery which would possess none of the objectionable features of the ordinary form, and at the same time do the same amount of work as that required of the office stationary battery. The cell is a form of the chloride of silver cell, of sufficient power to give

an electro-motive force of 1 volt, and an ampèreage of  $\frac{8}{10}$  ampère; so that a battery of 50 cells will do the same amount of work that 36 to 40 Leclanché cells will accomplish. Next to treatment of uterine fibroids by galvanism, he said he had found the greatest satisfaction in treating inflammatory exudates of the pelvis, the best results being obtained in these cases from comparatively strong doses, of from 75 to 125 milliampères. His experience in the treatment of uterine fibroids by electricity amounted in round numbers to 200 cases. Of this number not more than five failed to continue the treatment until results could be estimated, and of the remainder, but three had failed to obtain relief, and there were no deaths. His methods, except in unimportant minor details, were derived directly from Apostoli.

DR. G. BETTON MASSEY spoke particularly of the good effects of electricity in chronic inflammation of the uterus and of the endometrium. Having referred to several cases in illustration, he remarked that in simple endometritis or uterine catarrh, galvanic currents locally applied are practically infallible; so that he has never seen a case resist them. Out of twenty-six cases of fibroid tumor in which he had employed electrical treatment, two were cured anatomically and symptomatically, seven were cured symptomatically and anatomically reduced, eleven were greatly improved, four were slightly improved, one remained unchanged, and one died. He said he could not agree with Dr. Mundé in regard to the milliampère metre. In regard to the use of electricity in pyosalpinx, he had met with one instance in which the treatment for endometritis to which he had referred had excited a flow of pns.

A communication received from Dr. A. J. C. Skene, of Brooklyn, was then read, in the course of which he said that he had observed that those who had avoided the extremes of praise and condemnation in reference to the electrical treatment of fibromata were gaining in numbers and adding valuable notes to their clinical records. The strongest opponents, he believed, were those who knew least about electro-physics and the therapeutic use of electricity. Perhaps the most important question in the whole discussion, he said, was the relative merits of this and other methods of treatment. The claims of hysterectomy and the removal of the ovaries in cases of fibromata had been urged with great vigor by those strongly addicted to surgery; and by a curious use of the facts, it had been made to appear that surgical treatment had advantages, when such was not really the case. He had hoped to get the records to show that more cases have died from removal of the uterus and ovaries for the cure of fibromata than have died from these growths without treatment of any kind. If such were the facts—and he believed that the records of New York and Brooklyn would show that they were true—surely

surgery did not compare so favorably with electro-therapeutics.

DR. H. J. BOLDT thought that while electricity would not in every instance even alleviate the symptoms, we ought not to perform a radical surgical operation in any case until this had been given a thorough test. As regards pyosalpinx, however, he believed that the patient was cured when the tubes had been cut out by laparotomy, and not till then.

DR. GOELET then said that he had cured at least thirteen cases by galvano-puncture which could not have been otherwise relieved except by laparotomy. That is to say, the patients would otherwise have been mutilated. He thought it only right to try and cure these patients before mutilating them, and he had found that by emptying the tubes and the subsequent use of the current the tubes might be rendered patent. The resolution of the proximal end of the tube, he said, could be secured by galvanism of the endometrium, and he was very glad to learn that in this particular his experience had been confirmed by Dr. Massey in the case which he had related. He did not think that we ought to say that the removal of the tubes was a cure of pyosalpinx. It was a mutilation, and not a cure, and in many cases, indeed, the patient's condition was more embarrassing after the operation than before. He went on to say that many of the failures with electricity which Dr. Mundé stated he had met with were to be attributed to the fact of his having used his currents too weak.

*Stated Meeting, June 5, 1889.*

DR. CHARLES E. HAGNER, PRESIDENT, IN THE CHAIR.

DR. J. M. TONER entertained the Society with a description of the topography of Johnstown, showing that escape was impossible during the recent flood. Several of his relatives and his two instructors in medicine had been lost.

DR. D. W. PRENTISS presented *Casts of the Feet from a Scarlet Fever Patient*.

DR. HENDERSON read a paper on

#### CEREBRO-SPINAL MENINGITIS COMPLICATING PREGNANCY.

I was called Friday, March 29, 1889, to see Mrs. E., white, æt. 22 years, married, and found she had been sick for several days. She was seven months advanced in her second pregnancy. On the previous Tuesday she had fatigued herself very much by scrubbing up her room, and had suffered with pain in her head all that afternoon and the next day. On Thursday she had a violent chill, followed by fever, and on Friday, the

day I was called to see her, she had another chill. Her condition when I saw her on Friday afternoon was as follows: She was unable to retain anything on her stomach and was vomiting almost constantly a bitter greenish fluid. Her temperature at the time of my visit was  $103^{\circ}$ , her pulse 120, and she complained greatly of pain in her head and back. Supposing I had a case of remittent fever to deal with, I ordered a powder of  $\frac{3}{8}$  gr. of calomel every two hours, as she had constipated bowels, and gave her a suppository of 5 grs. of quinine every four hours. On visiting her the next morning I found that the vomiting still continued and that her bowels had not moved. She now complained very much of pain in her head and in the back of her neck and said she could not stand it any longer. I gave her a hypodermatic injection of  $\frac{1}{4}$  gr. of morphia, and no relief following I repeated the injection in half an hour. I ordered large enemata of soap and water to open the bowels, and said I would see her again in the evening. When I called I found that her bowels had been freely moved by the enemata and the vomiting had ceased, but she had had no sleep and still complained of pain in her head and neck, and also of an inability to move her head, which was now thrown backwards. Her temperature was at this time  $104^{\circ}$  and her pulse 130. I then recognized the true nature of the disease I had to contend with. The calomel powders and the suppositories of quinine were discontinued and she was ordered bromide of potash and chloral every two hours, and cold applications were applied to her head. When I visited her Sunday morning I found her much worse. Her temperature was  $106^{\circ}$ , pulse 140, and her delirium, which had been only occasional previous to this date, was now constant, and it was very difficult to get her to take either medicine or nourishment, as she experienced great difficulty in swallowing. Her body as well as her head (which was stiff from the rigidity of the muscles), was bent backwards to a marked degree. Her mouth and nose were covered with a herpetic eruption, and her eyes were suffused and inflamed. The movements of the fetus could be distinctly felt, and the advisability of inducing premature labor was considered. I ordered 5 grains of antipyrin every two hours until perspiration was noticeable. After taking one of the antipyrin capsules she went to sleep, and in a few minutes was seized with what her attendants called a convulsion, and I was hastily summoned. I found her in a state of wild delirium, and her head was constantly moving from side to side. Her delirium assumed a strong phase. She was incessantly counting from one to one hundred, and then back again to one, and the same thing over and over again. The convulsion, if she had one, had passed off. Her breathing was rapid and her temperature was still  $106^{\circ}$ . The family having requested a consultation, Dr.

J. F. R. Appleby was called in to the case. He agreed with me as to the nature of the disease after having satisfied himself it was not a case of uræmic poisoning, by drawing off the urine and examining it with the heat test, and finding no albumen present.

At the suggestion of Dr. Appleby a large enema of a quart of ice water was used with the hope of reducing the temperature. After the first enema her temperature was taken and found to be  $104^{\circ}$ . Another was now used with the result of the temperature falling to  $102^{\circ}$ . She then seemed to be more quiet and appeared more intelligent, and the bromide and chloral were continued with the result of her having several hours sleep. For the next few days her condition remained nearly the same, except that her temperature did not rise above  $103^{\circ}$ . It was almost impossible to give her food or medicine by the mouth because of her difficulty in swallowing, so nourishment consisted of whiskey and milk and of beef tea was given her, enemata, and the medicine in small and often repeated doses by the mouth. A large blister was applied to the back of her head and neck. On Wednesday she was unconscious but at times seemed to have rational moments, and it was then noticed that she had contractions of the uterus, and making an examination I found she was in labor, and that afternoon she was delivered of a seven months' fetus which was living.

The mother was entirely unconscious of its birth and remained so afterwards. Her pulse continued to grow more rapid and feeble, purpuric spots appeared on her limbs, and three days after the birth of the child, and on the tenth day of her illness she sank into a state of coma and died. The baby lived for ten days and then died from congenital debility. It would be an interesting subject to find out if possible the cause of this unusual disease in this patient. She was of a nervous disposition and had always suffered with insomnia and was very delicate. Her surroundings were very unhygienic, and her room had an odor about it like that of a cellar, and was very damp. I mention this as a possible predisposing cause. No post mortem was allowed, so I am unable to report the pathological conditions that would have been found.

DR. GEO. L. MAGRUDER reported two cases:

1. *A Turkey Quill Removed from the Urethra of a Boy.*
2. *A Hair-pin Removed from the Bladder of a Girl.*

DR. THOMAS N. McLAUGHLIN read a paper on

#### THE THERAPEUTIC EFFECT OF SULPHIDE OF ARSENIC IN DISEASES OF THE SKIN.

This paper is a preliminary report of some investigations which I have been conducting for the purpose of ascertaining the therapeutic effects

of sulphide of arsenic. My attention was attracted to this drug some time ago, and as I desired to obtain a preparation of arsenic which would be better tolerated by some of my cases, I was induced to give this preparation a trial. The sulphide of arsenic is used principally in the manufacture of fire-works, and for medicinal purposes has been seldom employed. The results which I have thus far obtained fully warrant me in calling your attention to the good effect which has followed the use of this drug.

Hurtz informs us that (Realgar) arsenic disulphide,  $As_2S_3$ , occurs in nature in the form of transparent red crystals, which belong to the type of the oblique rhombic prism. It is obtained as a red mass having a conchoidal fracture by melting 75 parts of arsenic with 32 parts of sulphur. It is fusible and may be crystalized by slow cooling. When strongly heated in closed vessels it boils and distils without alteration, but when heated in the air it burns into arsenious and sulphurous oxide. Three compounds of sulphur and arsenic are known: Arsenic disulphide,  $As_2S_3$ , or Realgar; arsenic trisulphide, or orpiment,  $As_2S_3$ ; and arsenic pentasulphide,  $As_2S_5$ . It is to the first of these preparations that I shall call your attention.

Since I was unable to obtain any but the crude drug in this city I ordered from Schieffelin & Co., of New York, 1,000 granules at a time, each containing  $\frac{1}{100}$  gr., and prescribed them in the following cases:

The first case, one of psoriasis. This patient had been under the care of some of the most distinguished men in this country. The various preparations of arsenic usually prescribed in the treatment of such cases had all been employed at various times during the twenty years which this patient has suffered with this disease. He has always been compelled, after a very short time, to stop the arsenic on account of the irritation which it invariably produced. He has never been able, therefore, to continue any of the arsenical preparations on this account. Every form of treatment has been employed in this case. I placed this patient upon one granule three times a day, and after four days increased the number to two granules three times a day, and in this way the number has been increased until he is taking eight granules three times a day. When I began to employ this drug the patient suffered with an eruption over his arms, back, head and forehead, his hands were covered with fissures, which would bleed whenever the fingers were extended, the tissue upon palmar surfaces frightfully indurated, the nails black and roughened.

His hands have greatly improved, his nails have nearly assumed their natural appearance, the fissures have entirely healed, and the face at the present time is practically well. One month after prescribing these granules my supply was

exhausted and the patient was compelled to do without them for one week, and during this period the eruption began to extend and the case lost nearly all the good effect which had been produced by the previous treatment. When he again began to use the granules the eruption, after a few days, began to show the effect of the treatment. The same local treatment has been continued all the time. This patient is in a better condition to-day than he has been at any time since the disease first appeared. There has not been the slightest irritation produced by this drug. His general health has improved, and he is now hopeful that he has obtained a remedy which may perhaps exert a controlling influence, if not a curative effect, in his case.

The second case of psoriasis had existed for six years. He has been treated by some noted specialists in this section of the country, and has not been benefited to any extent. This patient, a physician, is covered with an eruption from his head to his feet. He has never been able to take any of the arsenical preparations for a longer period than a week without serious gastric and intestinal irritation being produced. He has employed all forms of local treatment. When he called to see me he was disheartened, said that he had been trying the different forms of treatment during the past six years, and he had not observed the slightest improvement—the eruption appeared to be extending. I prescribed the granules as in the former case. He has not employed any local treatment to certain portions of the body, as I desired to see what the internal treatment alone would produce. He has been under treatment for eleven weeks, is at present taking eight granules three times a day, and the eruption is fading very rapidly. There has not been the slightest stomach or intestinal irritation. Large sections which were covered with the eruption are entirely clean, but show where the eruption has existed.

I have prescribed the granules in cases of acne and furuncles, where I have been in the habit of giving sulphide of calcium, and the results have been more satisfactory from the arsenic than from the latter.

In eczema I have also obtained satisfactory results. I have employed this drug in a large number of cases, and I have not in a single instance observed the slightest irritation or contra-indication to its use. These cases have all been of a very chronic character, and I have been careful to give it a severe and thorough test. I have found, during the short period which I have employed this drug, that the combined action of arsenic and sulphur, the latter proving one of the most serviceable drugs in the treatment of skin diseases, is far superior to the single action of either of these drugs.

The patient is entirely unaware that arsenic is

being administered, and this in itself is quite a consideration. The dose can also be conveniently increased or diminished, as the case requires, and finally entire absence of any irritation of the stomach or intestines thus far having been produced.

## FOREIGN CORRESPONDENCE.

### LETTER FROM PARIS.

(FROM OUR REGULAR CORRESPONDENT.)

*The Water of the Seine as a Causative of Typhoid Fever in Paris—Prof. Verneuil on the Immediate and Remote Results of Operations practiced for Local Tuberculosis—Extirpation of the Larynx—Codeine to obtain Anæsthesia—Dr. Ricord's Will.*

It has often been asked whether the ravages made by typhoid fever among the Parisian population are not attributable to the water of the Seine which they are sometimes condemned to drink. In a report on this question, addressed to the Prefect of Police, the Council of Hygiene and of Public Salubrity pronounced its opinion in the affirmative. After having established that potable water is, in large cities the vehicle of typhoid fever, and that the distribution of water non-contaminated diminishes the number of cases of this malady in a proportion hardly credible. The reporter, Dr. Auguste Ollivier, arrived at this conclusion that as far as the water supply is concerned the sanitary condition of Paris is most unsatisfactory. He established that the mortality by typhoid fever rises or diminishes in a direct ratio with the consumption more or less great of the Seine water. In 1888, for example, the minimum number of cases of fever occurred in the month of March, it remained stationary in May and June. From the 9th of June, 300,000 persons drank the Seine water, the mortality rose from 50 to 81. From the 20th of June, the supply of the Seine water was stopped, and the mortality fell again, in August, to 52. In 1889 the distribution of the Seine water commenced on the 25th of May and it has continued. The number of deaths rose from 52 to 115. This proportion has been maintained, as the distribution of the Seine water was continued. There were 110 deaths in July, 117 in August, and 53 during the first half of September. To remedy this deplorable state of things, the Council of Hygiene demands that the supply of pure water should be considerably augmented, by the acquisition of new springs, recognizing, however, the numerous obstacles which are opposed to the realization of this measure. The reporter proposes as an expedient, in anticipation of water being brought to Paris from new springs, that a strict supervision of the drinking water collected in the reservoirs should be carried out, and care

should be taken that this water should serve for nothing else than alimentation and should be suppressed for industrial purposes. In order to carry out this object, a double canalization should be established, with one cock much smaller than the other for spring water, while the second be reserved for the Seine water for washing purposes.

One of the most important questions brought before the recent Congress of Surgery had for its author Professor Verneuil, who treated of the immediate and remote results of operations practiced for local tuberculosis. Whilst acknowledging the immediate benefits of the operation, the eminent surgeon of the Pitié Hospital does not admit that it is always inoffensive. As to the remote results, Dr. Verneuil thinks that most frequently they are unfavorable. He remarked that one never meets in the hospital individuals that had been amputated since 10 years for a tuberculous lesion, when one is led to conclude that in ten years all the amputated tuberculous subjects are dead. The greater number of the members of the Congress were agreed in considering the operations as useful in tuberculous subjects as they are in other individuals, they did not think that they were more dangerous in the former and they expressed a doubt as to the influence of phthisis on evolution of wounds. They were, however, reserved as to the remote results of the operations.

The surgical treatment of peritonitis was considered a modern triumph, the subject gave rise to numerous important communications.

Dr. Cemons, of Bordeaux, presented to the members of the Congress a person on whom he had performed the operation of extirpation of the larynx, about 3 years ago, and who is none the worse for the operation. Since the operation, the man has resumed his occupation and breathes with the aid of a canula.

The employment of cocaine to obtain anæsthesia, or, better, local analgesia, had furnished Dr. Reclus the subject of practical considerations. He stated that notwithstanding his repeated communications he was sorry to find that cocaine had not entered into current practice; it was reproached as being inefficacious and dangerous. He had practiced upwards of 700 injections of cocaine with the view of producing analgesia, on which he made the following reflections: Intradermic injections alone are efficacious, cutaneous paintings have no effect, paintings of the mucous membranes alone may be utilized exceptionally for certain slight operations. Cocainized injections in hydrocele and old hydrarthrosis have given the best results. Interstitial injections alone have a veritable value in the operations on the integuments, but precaution should be taken to push the injection into the thickness of the skin, and not into the subcutaneous cellular tissue. If the soft parts, through which the needle

should pass, are very thick, it would be advisable to practice several superposed injections. In these conditions analgesia is always obtained, and these injections are not, as has been said, inefficacious in inflamed tissues. As regards the duration of the effect obtained by these interstitial injections thus practiced, the author has seen these effects continue for three-quarters of an hour and even one hour; he had effected radical cures without any pain. The bones do not seem to be susceptible of this calming action. In ano-rectal affections and in the painful operations that they necessitate the use of interior tampons imbibed in a 2 per cent. solution and a series of interstitial injections ensure a complete analgesia to such a degree that the dilatation of even the rectum becomes possible without pain. As to the dangers of which cocaine is accused, the author affirms that he had practiced 700 operations without any accident. Very complete bibliographical researches have revealed only four deaths, and in these cases considerable doses of cocaine were injected, namely, 75 centigrams, 1 gr. 20, 1 gr. 25, and 1 gr. 25. Below 75 centigrams there have never been any grave accidents. Certain accidents, however, do sometimes occur, such as pallor of the face, loquacity, tendency to syncope; but with ordinary doses, such as 20 centigrams at most, accidents are very rare. In short, from 10 to 12 centigrams, or 5 Pravaz's syringefuls of the solution, most commonly suffice. To sum up, the author considers cocaine an excellent substance, faithful and efficacious; it is sufficient to handle it with precaution, as is necessary with all the other alkaloids at the disposal of the medical man.

By his will the late Dr. Ricord has left, among other legacies, 10,000 francs to the Academy of Medicine for the foundation of a biennial prize, 5,000 francs to the Société de Chirurgie for a similar purpose, and 10,000 francs to the Association Générale des Médecins de France. To the Midi Hospital he has bequeathed his splendid library, in memory of his twenty-nine years' service as surgeon and teacher in that hospital, to which he owed his reputation and his wealth. It is proposed to perpetuate his name in a similarly appropriate manner in connection with the scene of his scientific labors and triumphs by calling the Hôpital du Midi the Hôpital Ricord.

Professor Richet has resigned his position as surgeon to the Hôtel Dieu on the ground of old age and infirmity.

A. B.

ASSOCIATION OF AMERICAN ANATOMISTS.—The second meeting of the Association of American Anatomists will take place in the Biological Department of the University of Pennsylvania, December 26, 27 and 28. The profession is cordially invited to attend the meetings.

## BOOK REVIEWS.

### ANNUAL OF THE UNIVERSAL MEDICAL SCIENCES.

Edited by CHARLES E. SAJOUS, M.D., and Seventy Associate Editors, assisted by over two-hundred Corresponding Editors, Collaborators and Correspondents. Illustrated with Chromo-Lithographs, Engravings and Maps. Five Volumes. Philadelphia, New York and London: F. A. Davis, 1889.

We venture to say that all who saw the Annual as it appeared in 1888 were on the lookout for its reappearance this year; but there are many whose knowledge of this magnificent undertaking will date with this present issue, and to those a mere examination of the work will suffice to show that it fills a legitimate place in the evolution of knowledge, for it does what no single individual is capable of doing. It aims to preserve the useful and discard the useless in all the multiple branches of medical science. Its function is selective, developed of necessity, by the superabundant medical literature of the day. We feel that a work of this class will grow in usefulness with each succeeding annual issue.

These volumes make readily available to the busy practitioner the best fruits of medical progress for the year, selected by able editors from the current literature of the world; such a work cannot be overlooked by anyone who would keep abreast of the times. Even the knowledge picked up by the habitual journal reader, who runs over six or eight periodicals weekly, cannot be compared with what may be acquired with these volumes which represent the most useful, promising and novel developments in the whole field of medical science that have materialized during a year.

The contents of these five volumes consists of matter which has been taken largely from the current numbers of seven hundred and fifty-six different journals, to which might be added books, theses, monographs, etc., numbering two hundred and thirty-four. These are referred to in the text by date and number, thus giving an unusually wide range of bibliographic material.

No pains have been spared to make the indices as complete and accurate as possible. The weights and measures both Metric and Apothecaries, Farenheit and Centigrade, appear side by side.

Deluged with such a mass of periodical literature as the references in this work show us to be, it would seem almost impossible, without the aid of some such shifting process, to know where we stand in regard to many disputed questions, or what the value of this or that alleged new discovery is. Now every intelligent man wants to hear the evidence, weigh the authority and judge for himself. It would appear that the editors

have acted as impartial collectors of evidence and submit the result of their labor to the judgment of the reader.

With so much that is worthy of notice incorporated in one work, and each department written up with a minuteness and thoroughness appreciated particularly by the specialist, it would avail nothing to cite particular instances of progress. Let it be sufficient to say, however, that while formerly there was a possible excuse for not having the latest information on matters pertaining to the medical sciences, there can no longer be such an excuse while the *Annual* is published.

**THE CURE OF CROOKED AND OTHERWISE DEFORMED NOSES.** By JOHN B. ROBERTS, A.M., M.D., Professor of Anatomy and Surgery in the Philadelphia Polyclinic, etc. Philadelphia: P. Blakiston, Son & Co. 1889. Pp. 24.

This is a reprint in book form of a paper read before the Philadelphia County Medical Society, and contains some useful hints on the subject of rhinoplasty.

**TRANSACTIONS OF THE MICHIGAN STATE MEDICAL SOCIETY.** Twenty-fourth annual meeting, held in Kalamazoo, June 9 and 10, 1889: pp. 390.

The work of the Michigan State Society for 1889, as indicated by its published transactions, is deserving of very high praise. Thirty-five papers, covering a wide range of topics, were read at the annual meeting. Although this is not a large number, it is but just to say that the material is of a high order of excellence. Most of the papers are accompanied by the discussions which followed their reading. In point of quality of work done, this Society deserves to rank among the foremost of the State Societies.

**ALCOHOL INSIDE OUT.** By ELISHA CHENERY, M.D., Member of the American Medical Association, Fellow of the Massachusetts Medical Society, etc. Philadelphia: Records, McMullin & Co. 1889. Cloth, price, \$1.50; pp. 340.

Dr. Chenery has considered his subject from the standpoints of chemistry, physiology, pathology and experience, and has presented it in very able form. It is not addressed particularly to the medical profession, but "to the millions." The topics considered are the following: Alcohol, what and whence is it? Alcohol, its way through the system, with observations by the way; Alcohol as a poison, a food, a medicine. In its claims as a food and medicine alcohol receives pretty rough treatment from the writer, who removed his gloves for this purpose. He does not regard it as in any sense a food, or even an "accessory food," by any just interpretation. As a medicine some of its claims to applicability in external and

internal medication are admitted; but inasmuch as all its uses are impaired by serious drawbacks, and since other remedies are of equal or superior merit, the writer feels that it may as well be discarded from the *materia medica*. "On the whole," he says, "alcohol is foreign to the human body, both in nature and in action—an enemy. Alcohol will not destroy itself, nor can its few virtues redeem it in the face of its exceeding hostility to the race. Banishment is its due."

Throughout the entire work the author's citations are extremely numerous. Particular attention is due to the excellent chapter on the adulteration of the various vinous and spirituous liquors in use.

**A TREATISE ON THE SCIENCE AND PRACTICE OF MIDWIFERY.** By W. S. PLAYFAIR, M.D., LL.D., F.R.C.P., Physician-Accoucheur to H. I. and R. H. the Duchess of Edinburgh, Professor of Obstetric Medicine in King's College, Consulting Physician to the General Lying-in Hospital, London, etc. Fifth American, from the seventh English edition, with notes and additions by ROBERT P. HARRIS, M.D. With five plates and 207 illustrations. Philadelphia: Lea Brothers & Co. 1889. Pp. xxxi, 670. Price, leather, \$5.00.

But little can be said that will tend to increase the cordiality of the reception that is assured in advance for such an old and excellent friend as Playfair's *Obstetrics*, which stands in the first rank of English works on this subject. The present edition follows closely upon the sixth, and accordingly the author has not deemed it necessary to make any very extensive additions to his earlier editions. We regret, nevertheless, that he has not seen fit to enlarge upon the general subject of child-bed fever, the bacteriological aspect of which is decidedly slighted, while the relation of puerperal cellulitis and peritonitis to septic infection is scarcely indicated, these two manifestations of disease being treated almost as separate entities independent of any connection with infectious processes. The footprints of the American editor appear in greatest abundance upon the pages devoted to a consideration of the various modifications of the Cæsarean section, upon which questions Dr. Harris has been afforded abundant opportunity to improve upon the English edition, an opportunity of which he has availed himself with commendable judgment.

**THE STORY OF THE BACTERIA AND THEIR RELATION TO HEALTH AND DISEASE.** By T. MITCHELL PRUDDEN, M.D. Pp. 143. New York and London: G. P. Putnam's Sons. 1889.

Every one who has read Prudden's "*Manual of Practical Normal Histology*" is well aware what a large amount of useful information this author

is able to condense in small space. In the present volume he has treated an essentially scientific subject in a popular manner with the avowed purpose of suiting it to the understanding of non-professional readers. This has been done in a most satisfactory and praiseworthy manner. Nothing can be more fascinating than the unfolding of the mysteries of nature before the eyes of the eager searcher for knowledge, and in this small work the author reveals a chapter of nature's secrets which has only been brought to light in very recent years, and of which the general public has as yet extremely little information. It is written in a very simple and untechnical style, but containing as it does much information regarding the bearing of recent investigations, as well as a brief survey of the general scope of the subject, it will be found to possess no small value to medical readers.

SAUNDERS' QUESTION COMPENDS NO. 7. ESSENTIALS OF MATERIA MEDICA, THERAPEUTICS, AND PRESCRIPTION WRITING. Arranged in the Form of Questions and Answers, prepared especially for Students of Medicine. By HENRY MORRIS, M.D., Late Demonstrator, Jefferson Medical College; Co-editor Biddle's *Materia Medica*; Visiting Physician to St. Joseph's Hospital, etc. Pp. xvi, 250. Price, cloth, \$1. Philadelphia: W. B. Saunders. 1889.

We believe that quiz compends, when of as high an order of merit as this one, offer substantial advantages to students in facilitating the process of memorizing a vast number of facts and figures. We can hardly agree with the author that this volume is valuable in placing before the student the *principles* of materia medica and therapeutics, but are entirely willing to concede the value of the method employed in setting forth the practical *facts* based upon those principles.

Most of the new remedies receive a proportionate share of attention, and not students alone, but busy practitioners as well may profit by such a survey of the whole field of materia medica as is afforded by the compact arrangement of this convenient work.

## ASSOCIATION NEWS.

### American Medical Association—Forty-first Annual Meeting.

#### *Section of Obstetrics and Diseases of Women.*

The officers of the Section of Obstetrics and Diseases of Women respectfully request those who desire to read papers in that Section at the meeting of the American Medical Association to be held in Nashville, Tenn., May 19-22, to com-

municate the titles thereof to either of the undersigned not later than January 15, 1890.

WILLIAM WARREN POTTER, Chairman,  
284 Franklin St., Buffalo, N. Y.

Williams, Boston; Surgeon-General U. S. Army, Washington; Battle & Co., St. Louis, Mo.; Geo. F. Lasher, Philadelphia; Dr. C. F. Falley, Brattville, Ky.; E. B. Wilson, Collierville, Tenn.; Dr. U. M. L. Rickards, Philadelphia; Lutz & Movius, John O. Meade, King's Medical Advertising Agency, New York; W. Muset, Brooklyn, N. Y.; John Wanamaker, Philadelphia; Dr. C. E. Spencer, Fort Gratiot, Mich.; B. Westermann & Co., New York; Dr. F. B. Lovell, Daykin, Neb.; I. Haldenstein, The Maltine Mfg. Co., New York; Dr. Jos. L. Bauer, St. Louis, Mo.; Dr. James French, Cincinnati, O.; Félix Alcan, Paris, France; Frank S. Billings & Co., Chicago; Dr. Max Thorner, Cincinnati, O.; Dr. L. D. Frum, Scardis, W. Va.; Dr. W. J. Coppernall, South Butler, N. Y.; Dr. Joseph Jones, New Orleans, La.

### *Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from December 7, 1889, to December 13, 1889.*

Major John D. Hall, Surgeon, is granted leave of absence for ten days, to take effect upon being relieved from duty at Ft. Niagara, N. Y. Par. 11, S. O. 285, A. G. O., Washington, December 7, 1889.

By direction of the Secretary of War, Capt. Edward C. Carter, Asst. Surgeon, will be relieved from duty at Willett's Point, N. Y., upon the arrival at that station of Major Clarence Ewen, Surgeon, and will then proceed to Ft. Walla Walla, Wash., and report in person to the commanding officer of that post for duty, reporting also by letter to the Commanding General, Dept. of the Columbia.

### *Official List of Changes in the Medical Corps of the U. S. Navy for the Week Ending December 14, 1889.*

Surgeon J. W. Ross, detached from Navy Yard, Pensacola, Fla., and placed on waiting orders.

Asst. Surgeon I. W. Kite, detached from Naval Hospital, Philadelphia, and to Navy Yard, Pensacola, Fla.

Surgeon B. F. Rogers, ordered to special duty at Norfolk, Va.

P. A. Surgeon Philip Leach, ordered to duty at Naval Academy, Annapolis, Md.

### THE NECESSITY OF SANITARY SUPERVISION OF SCHOOLS.

*Read in the Section of State Medicine at the Fortieth Annual Meeting of the American Medical Association, June, 1889.*

BY GEORGE H ROHE, M.D.

PROFESSOR OF OBSTETRICS AND HYGIENE IN THE COLLEGE OF PHYSICIANS AND SURGEONS OF BALTIMORE.

It is well known to physicians and others who have devoted attention to the subject, that many of the most disabling, painful and destructive maladies owe their origin or intensification to certain injurious influences of school life. Inasmuch as a good system of intellectual training should endeavor to avoid injury to bodily health, it becomes worth while to inquire what these injurious influences are, and whether they can be avoided, mitigated or removed.

Authorities in school hygiene assert that bad construction of school-houses, defective lighting and ventilation, inefficient removal of the bodily excretions or of the pernicious gases generated by their decomposition, improper school furniture and furnishings, such as seats, desks, blackboards, books, etc., deficient facilities for drying wet clothing, want of elementary knowledge of hygiene on the part of the teacher, over-study, carelessness on the part of parents or attending physicians, and many other causes needless to specify, are responsible for a large number of serious diseases, among which the following are the more important:

1. Nearsightedness.
2. Pulmonary consumption.
3. Spinal deformities.
4. Nervous and digestive disorders.
5. Contagious diseases.

#### I. NEARSIGHTEDNESS.

It needs no argument to show that nearsightedness is increasing. The large proportion of young persons compelled to wear glasses in order to use their visual organs to the best advantage testifies to this with sufficient emphasis. There is abundant evidence also to prove that this increase is due to the pernicious influences of certain unhygienic conditions to which children are sub-

jected in the schools. For example: It has been shown, basing the conclusions upon the examination of nearly 100,000 school children in Germany and elsewhere, that in village schools less than 1 per cent. of the pupils are nearsighted; in the elementary schools in cities, from 2 to 3 per cent., and in the grammar and high schools, from 4 per cent. in the lowest classes to over 50 per cent. in the highest. The percentage in some high schools and colleges reached a much higher figure, being 75 per cent. in one school in Vienna. Drs. Loring and Derby found a similar progressive increase in nearsightedness in the public schools of New York, although not to as great an extent as European observers have found. But it is not merely the proportion of nearsighted pupils that increases in the higher classes; the *degree* of the abnormality increases likewise, so that a pupil entering school with healthy eyes and normal vision will at the end of two years have a minor degree of nearsight, which in two or three years more will increase to a much higher degree, thus proving conclusively that the exigencies of school life determine the causation of the affection.

But it may be objected that this visual defect is a necessary accompaniment of school work, and that it cannot be avoided without entirely giving up educating children, or reducing their education to a minimum. To disprove this objection certain evidence is on record which could not be more apropos if the experiment had been made purposely. In the city of Coburg 2,323 children were examined in 1874, and showed an average of 21 per cent. of nearsighted pupils. The same number examined in 1877 showed an average of only 15 per cent. This marked reduction was accomplished by a better arrangement of seats and by better lighting in the schools. In some of the new schools erected between 1874 and 1877, in which hygienic principles were applied, the reduction in the proportion of nearsighted pupils was even greater than is shown by the average.

As the tendency to nearsightedness is hereditary and progressive, the time must come when the great majority of educated people will be nearsighted, unless measures are adopted to check its increase. The principal causes of nearsightedness in schools are:

1. Improper construction of seats and desks. A line dropped from the near edge of the desk should strike the front edge of the seat; if there is an interspace between the line and the seat the pupil cannot sit erect while writing or reading from a book resting on the desk. He is obliged to lean over forward, causing congestion of the eyes and consequent succeeding visual anomalies.

2. Bad lighting. An insufficient quantity of light or an improper position of the pupil with reference to the source of light. In a properly arranged schoolroom the light should come from the left side and a little above and behind the pupil. Daylight, which should be the only sort of light used in schoolrooms, should be diffused, and not enter the room as direct solar rays. This requires that the side of the room from which the light enters should face toward the north, in order to avoid direct sunlight. The proportion of clear window space to floor space should be as 1 to 5.

3. The distance of the objects to be seen, for example maps and blackboards, and their position with reference to the light. Letters and figures of the size usually made on blackboards can not be seen with normal vision at a greater distance than 30 feet. Hence, if the blackboard is placed at a greater distance, or the writing on the board is indistinct, the attempts to accommodate the eye to the greater distance will cause strain or other visual troubles.

4. Type, paper and printing of school books. No type of a smaller size than that known to printers as "long primer," leaded, should be permitted in any text-book. The paper should be clean and not translucent. Colin, the highest authority upon this subject in the world, says that the school authorities should place every school book upon the *Index prohibitorum* in which smaller type is used than long primer, a less interval between lines than  $\frac{1}{16}$  inch, a longer line than  $4\frac{1}{2}$  inches, and more than 60 letters to a line. He also says, with reference to the custom of printing matters of less importance in small type, while other portions of the book are printed in larger type: "What is unimportant should not be printed at all; but what is important should be printed in type of proper size."

5. Length of time of study. Lessons should be frequently varied, and care taken that two writing lessons should not immediately follow each other.

## 2. PULMONARY CONSUMPTION.

Of the 8,936 deaths from all causes in Baltimore during the year 1888, 1,151, or almost exactly one-eighth, were from consumption. It is notorious that in a large proportion of cases the seeds of this fatal disease are implanted in the youthful system during school life. Now, inasmuch as it is undoubted that badly ventilated and lighted apartments, and an improper position

of the body, interfering with full expansion of the chest and free circulation, are strongly predisposing causes of consumption, it is important that the utmost attention should be paid to the removal of such conditions.

## 3. SPINAL DEFORMITY.

Five-sixths of the cases of spinal disease and deformity begin during the years of school life. The affection is over ten times as frequent in girls as it is in boys. Improperly constructed seats and an almost necessarily consequent bad posture of the body are responsible for the greater number of these cases. Defective lighting has often a decided influence in producing this disease by compelling the pupil to assume an improper position.

## 4. NERVOUS AND DIGESTIVE DERANGEMENTS.

These disorders, which frequently persist through life, rendering the individual a chronic invalid, are often results of defective ventilation, over-heating, or excessive mental strain. The influence of excessive brain stuffing in producing headaches and other nervous affections in school children has lately been called in question by teachers and others, who object to the pernicious activity of sanitarians in endeavoring to remove the bad conditions incident to school life. The results of an investigation by Prof. Bystroff, of St. Petersburg, show, however, that the influence of the customary intellectual *surmenage*, as the French style it, is not exaggerated. This author examined 7,478 boys and girls in the St. Petersburg schools during the last five years, and found headache in 868, that is, in 11.6 per cent. He states that the percentage of headache increases almost in a direct progression with the age of the children, as well as with the number of hours occupied by them for mental labor; thus, while headache occurred in only 5 per cent. of the children aged 8, it attacked from 28 to 40 per cent. of the pupils aged from 14 to 18. The author argues that an essential cause of obstinate headache in school children is the excessive mental strain enforced by the present educational programme, which leaves out of consideration the peculiarities of the child's nature and the elementary principles of scientific hygiene. The overstrain brings about an increased irritability of the brain and consecutive disturbances in the cerebral circulation. In view of these figures the appeal of a recent French writer for "un peu plus des muscles, un peu moins des idées" (a little more muscle, a little less brain) seems justified.

## 5. CONTAGIOUS DISEASES.

Sanitarians are practically unanimous in the opinion that the schools are frequent sources of the extension of contagious diseases. Small-pox, scarlet fever, diphtheria, mumps, measles and whooping-cough are probably spread as often

through the medium of schools as in any other way. Epidemics of these diseases always increase during the school season, and rapidly diminish when the schools are closed. Suspension of the schools has sometimes brought to an end epidemics of diphtheria which could not be controlled in any other way. The almost unrestricted manner in which children attend school from houses infected by one or other of the diseases mentioned gives the freest possible chance for the spread of these maladies. School boards usually require that all children attending school shall present a certificate of vaccination before being admitted, but it is an open secret that physicians have given such certificates without examining the arms of the children. What guarantee has the Board, what assurance have the parents of the thousands of other children that a child with such an uncertifying certificate may not come from an infected house, and so spread small-pox?

In what manner can the evils mentioned be removed or abated?

First, by securing proper construction, ventilation, heating, lighting and furnishing of school-houses; then by watching over the health of the pupils from the time of their admission to their graduation, correcting habits injurious to health, and preventing, by appropriate measures in conjunction with teachers, parents and the municipal health authorities, the spread of contagious or infectious diseases. This can only be successfully accomplished by the employment of an expert official appointed by the Board of School Commissioners and subject to their authority. I would indicate the scope of action and duties of such an official somewhat as follows:

An official, to be designated as "Sanitary Commissioner" or "Sanitary Supervisor of Schools," shall be appointed, whose duties shall be to examine all plans for new school buildings before construction, all new school-houses before acceptance, and all school buildings now in use, and suggest to the Board such changes as will make them more appropriate in a hygienic point of view. He shall examine all new pupils applying for admission, to determine whether they are vaccinated, vaccinate such as need it, keep a watchful care over the course of instruction, so that no children are over-burdened in their daily tasks, receive due notification, through the teachers or the health department, of any contagious disease among children attending the schools, or occurring in houses whence children are attending school, examine all text-books and give an expert opinion upon paper, type and print, and also upon the contents of such as pretend to give instruction in hygiene, before they are adopted. He shall give instruction, by lectures and otherwise, to teachers upon the principles and practice of school hygiene under such regulations as the

Board may establish, visit every public school-room at least four times in every year, and make such suggestions for sanitary improvement as appear necessary. He shall also test the eyes of all school children as to their vision at least once every year, and keep an accurate record of these tests. He shall report annually, in writing, to the Board of School Commissioners upon the work he has performed during the year. Special reports may be required from him at any time upon questions coming within the purview of his duties, and he shall be at all times prepared to aid the Board with advice and suggestions.

Manifestly such duties as here outlined can be performed only by an educated physician who has given especial attention to hygienic questions both in their general and special applications. It is obvious that political services do not necessarily qualify a man for such duties; hence his appointment should not be contingent upon his political views or activity, but upon his merits as a student of hygiene. It must be likewise manifest that a physician with a large practice, or a popular surgeon, or an obstetrician with a fashionable clientèle, are not necessarily the best qualified for this service; in fact the sanitary supervisor of schools requires knowledge of a special character which the practicing physician rarely possesses, be he never so competent or successful in his own special field.

There is a tendency among the wit-snappers of the press and, I am sorry to say, among the medical profession likewise, to deride school boards for their ignorance of the principles of school hygiene. I am inclined to think this criticism is often unjust to the men who at a sacrifice of their time and comfort assume the important trust of administering the affairs of public education. In my native city, where the School Board is selected by the City Council, I am sure every member of the Board is thoroughly imbued with the responsibilities of his position and anxious to do the best he can to advance the cause of popular education and the interests of the pupils for whom he is responsible. I have found these men anxious to learn in what manner they could more efficiently discharge their duties, and when a plan was suggested to them they eagerly adopted it and asked the city government for power to carry it into effect. I have no doubt that the boards of education in other cities are composed likewise of public-spirited men whose desire to discharge their duties honestly and creditably is above all desire for personal advancement. The plan which the Board of School Commissioners of Baltimore asked leave (which has, unhappily, not yet been granted by the city authorities) to carry into effect is outlined in the following quotation from the report of that body for 1887:

"It is undoubtedly the duty of those in charge of the public schools to do whatever may be

necessary for promoting the health of the pupils, as well as their intellectual development.

"It is unfortunately true that many children are subject to deleterious influences during their school life, which not only impede their progress in school, but often permanently impair their health; and if it is possible to do so, the causes of these results should be prevented or removed. With this view the Board has recently asked authority from the City Council to appoint an officer who shall be a physician and expert in sanitary science, and who shall have general supervision of the sanitary condition of the schools, and whose duties shall be as follows:

"1. To carefully examine all plans submitted for the construction of new school-houses, and suggest such modifications as may be necessary from a sanitary point of view.

"2. To advise with the Commissioners with reference to necessary alterations in school buildings to improve their hygienic condition.

"3. To examine all text-books before adoption, in order that the type, printing or paper injurious to the eyesight of pupils may be avoided in selecting such books.

"4. To satisfy himself, by personal examination if necessary, that all the pupils admitted to the schools have been properly vaccinated or otherwise protected against small-pox.

"5. To take such measures, in connection with the Health Commissioner of the city, as may be necessary to prevent the spread of contagious diseases in or through the medium of the public schools.

"6. To examine annually the eyesight of the children attending the public schools, and to keep an accurate record of such examinations.

"7. To report annually, or as often as may be required by the commissioners, upon the sanitary condition of the schools and of the pupils attending them, and to advise the commissioners upon sanitary questions connected with schools whenever required.

"8. To give instruction, by lecture or otherwise, to the teachers in the schools upon the elementary principles of school hygiene.

"The Committee on Health has earnestly recommended the appointment of a sanitary superintendent for the schools, and believe that great benefit would result to the pupils, if such officer is well qualified for the position and faithfully performs the duties as above prescribed, and the Board requests your favorable consideration of this application."

I am disposed to believe that the reason so little attention is paid to the subject of school hygiene by school authorities generally is owing to the indefinite manner in which the subject is often presented to those bodies. Advocates of sanitary improvement too often seem to think that mere assertion is all sufficient and will carry

conviction. This is a mistake. Facts must be collated and arranged in such a manner that their significance can not be otherwise than in their true relations, and it will then not be difficult usually to convince intelligent public men of their importance.

I trust that the members of the Section of State Medicine are fully imbued with the necessity of the reform in school administration which I have advocated. I am quite sure that the presentation of facts which I have made here was unnecessary to impress its importance upon you; but I would suggest that in any movement to secure the results which must flow from the adoption of these measures, the advocates will so fortify themselves with the facts at command as will enable them to present a case to the public in which the evidence is all relevant and the testimony unimpeachable.

DR. W. L. SCHENCK, of Kansas City, said: Though Dr. Rohé's discussion of his subject has been full and full of valuable information, it cannot be exhausted in twenty minutes. At the National Association of Railway Surgeons held the other day at St. Louis, prominent on the platform was displayed this sentiment: Surgery and Hygiene—the medicine of the twentieth century. Then this will be the Section of the American Medical Association. We sometimes sing:

"Youth is the time to serve the Lord,  
The time to receive the rich reward."

It is the time to lay the foundation upon which to erect a superstructure that shall stand and withstand; the time to develop strong and healthy bodies through which mind and soul shall find opportunity to serve God and man.

The author of the paper has very properly emphasized the importance of preventing schools from becoming depots for the reception and distribution of infectious and contagious diseases. They bring together children from all classes and localities, so that if the nidus of contagious disease finds lodgment in the district it may, without proper sanitary inspection and supervision, be carried to every home.

Childhood may or may not be more susceptible to such diseases than adult life, but its virgin soil has not had opportunity of exemption through contact and contract, and certainly some of the zymotic diseases, as scarlet fever, diphtheria and small-pox, are especially fatal in early life. The health interests of every community demands that our schools should have intelligent supervision, and at the first appearance of contagious disease separation and isolation, and always vaccination.

The children of all civilized nations spend a large portion of their time in the schoolroom, and if they escape its mortal perils they carry thence the physical, mental and moral development and habits that shall govern their future lives, hence we cannot too strongly impress the importance of scientific school hygiene.

In America schools are controlled by directors ignorant of sanitation and chiefly anxious about their economic arrangement, and as teachers reflect the sentiments of the directors, the difficulties do not lie so much in sanitary science as in the difficulty of impressing the people with its importance.

Take one of the simplest problems in sanitary science. Pure air is necessary to the oxidation and decarbonization of the blood, and is Nature's antiseptic and disinfectant. By its universal distribution Providence has so emphasized its importance that "a wayfaring man, though a fool, should not err," yet ninety-nine out of one hundred school buildings are without proper arrangement for ventilation, and too often where the architect has made proper provision the ignorance or stupidity of janitor or teacher thwarts his purpose. Some one who comprehends its importance should see that the schoolroom is constantly supplied with pure air, warmed before it is admitted and removed as fast as it is contaminated. Our schools fail alike to protect the health and life of children placed under their care for protection and development, and to teach them the importance and the methods of protection. Every school district is a field ripe for the scientific sanitarian. How shall teachers teach and apply that which they do not understand, and how shall they learn without a teacher? Every academy, normal school and college should have a department of preventive and State medicine, that their pupils may carry thence into the various departments of life the knowledge that shall enable them to protect themselves and the community in which they reside against disease and premature death.

There are many and varied sanitary questions of vital importance to the school, to parents and the State, whose neglect brings disease and death where there should be life, health and growth. Among the more important we might name the location of the school building with reference to air, light and water, soil, drainage and general surroundings, seats, and commodes, school methods, false stimulants to study, overwork, underwork, machine work; all bearing upon the physical and intellectual health and life of the pupil and proper subjects for sanitary inspection and instruction.

There is a time in the history of all civilizations when the belief prevails that physical punishment is the "schoolmaster to bring us to Christ," but as civilization advances we learn that "all his ways are wisdom's ways and all his paths are peace." In the United States, save at the hearthstone and in the schoolroom, the whipping post is abolished, and it only lingers there because cowards can flog unresisting infants with impunity.

In the city of Boston, which we were wont to consider in the forefront of civilization, though

the pupils in the high school, who are old enough to resist, are not flogged, 18,000 corporal punishments were administered last year in the grammar and primary departments of her public schools, and for the past five years the record shows the number of whippings has about equalled the number of pupils. What a commentary on our civilization! The only apology offered is that many of them were wild, which only demonstrates the fact that many of them could have been dispensed with. That they were not excessive is probably due to the fact that the temper of the teacher was under partial control. If any benefit can arise from the use of the rod it should generally be applied to the teacher who uses it. It is the story of the old Scotch minister. When a brother told him he had the sexton go around to wake up those who slept when he preached, the Scotchman replied "An' wad it na' be he better to wake up the minister." The rod is brutal and brutalizing. It debases mentally and morally both teacher and pupil. With every educational method the question must be, does it implant in the mind a desire for knowledge for the sake of knowledge, a desire to do right through love of right? Education on this basis always strengthens, uplifts, enlarges, is always hygienic. The true teacher, filled with the grandeur of his vocation, maketh his pupils "to lie down in green pastures, he leadeth them beside the still waters, he restoreth the soul." The rod is the measure of his incapacity. While we may not know the essence of spirit and are unable to say whether it is an original creation or whether monad, bivalve and simian marked the weary way to its coronation in man, we find it moulding and developing the tenement in which it dwells, and in turn through its agency being moulded and developed into grander proportions. Man is not a sphynx-like mixture of angel and beast, the possibilities of the angel lying in the mortification of the beast. The thought that the spirit is to be brought into subjection by the mortification and flagellation of the body finds no place in scientific hygiene. Aught that injures the casket injures the jewel it contains. The full and harmonious development of the spirit is through the perfect health and growth of the body, "*mens sana in corpore sano.*"

When the motive for spiritual growth is either hope of reward or fear of punishment, the end is attained only when the motive is removed. They dwarf and destroy the desire and capacity for perpetual growth and tend to moral, intellectual and physical disease. There is a wrong method and a wrong motive. Fear cannot develop true heroism, but tends to timidity, sullenness and revenge, and both lead to irritability, nervousness and physical disease. Aught that injures the spirit injures the body in which it dwells,

"For of the soul the body form doth take,  
For soul is form and doth the body make."

It is important to the State and to humanity that the schools where the children of the nation are placed for culture and growth should be under the constant supervision of those who understand the laws of life and all that tends to its deterioration.

DR. LINCOLN, of Massachusetts, said he had found the standards of all description vary according to the authority adopted. Even authorities differ, and hence we need the opinions of the best.

Resolutions regarding the formation of a committee to inquire into the advisability of securing such legislation as Dr. Rohé had suggested were introduced by Dr. Lincoln.

Resuming the discussion DR. PINKHAM, Chairman of Sanitary Committee for the schools in LYNN, Mass., said that he had been engaged in such work for several years, and his committee is granted for this purpose \$2,000 per year. He had found deficiency in ventilating and lighting in all the buildings under the supervision of his committee. Reports were made to the State Board of Health and many reforms have been carried out.

DR. BELL, of New York, said that some of the suggestions made had already proved impracticable. Thorough exposure of the evils is the most important way of abolishing an evil. The general sanitary authorities of the cities are getting stronger than the school boards, and properly so. In general the boards of education have opposed the necessary hygienic regulations.

DR. GIBON, U. S. N., said he had been a school inspector and had always found schools unhygienic; and furthermore, he had always been opposed in his work by the school boards. He supported Dr. Lincoln's resolutions.

The resolutions were then adopted and Drs. Lincoln, Rohé, Reed, Schenck, and Pinkham were constituted a committee to take the matter in hand.

## THE HUMORAL PATHOLOGY, OR TOXIC AGENTS IN THE BLOOD AS A CAUSE OF DISEASES OF THE NERVOUS SYSTEM.

*Delivered in the Section of Practice of Medicine, Materia Medica and Physiology, at the Fortieth Annual Meeting of the American Medical Association, June, 1889.*

BY M. R. CRAIN, M.D.,  
OF RUTLAND, VT.

It is unnecessary for me to go into the history of the humoral pathology, as held by physicians for so many centuries, with their crude and erroneous ideas, as well as the opposite doctrine which followed, *i. e.*, that all morbid processes originated in the solids.

The latter as an exclusive theory is equally absurd. Thos. Watson, after speaking of the two above named theories, says: "The pendulum of

opinion swung at once, as is usual, into the opposite extreme of error. It is now settling in our time at the juster median. Reviewing, under new and more faithful evidence, the humored doctrine again asserts its rightful, but modified claims upon our acceptance. That its old extravagances still find favor among the ignorant, and are commonly adopted by the quack, are circumstances which illustrate the fact that the mischievous influence of unsound theories survived the duration of the theories themselves. The scientific physician of the present day can only wonder how solidism or exclusive humoralism should ever have found advocates." Although the above was uttered by Watson more than forty years ago, few since that time have taken as candid view of the subject as he did, and the tendency has been towards solidism. The scientific mind of the present is very skeptical and accepts no vague theories. Everything must be proven, in fact must be perceived by the senses.

The microscope gave a great impulse to solidism by enabling us to discover lesions that could not be seen with the unaided eye, and to study the minute structure of coarser specimens. While this is true in general medicine, it has been carried to a much greater extent in neurology. The neurologists of the present and near past have been striving to find some change in the structure of the nervous tissue to account for every perverted function of the nervous system. Although I do not underrate the importance of studying the minute structure of pathological specimens in diseases of the nervous system, it is fully as important to try and ferret out the cause of the lesion, also, in cases where there is no change in structure, to find the cause of the perverted function.

In many cases the exciting cause of the change in structure and, where there is no change in structure, the perverted function, is some unnatural or toxic condition of the blood. Of course I do not wish to convey the impression that it is a new idea that organic disease or perverted function of the nervous system can be caused by a toxic condition of the blood. Far from it, for we are all familiar with the effects of alcohol or an excess of urea in the blood on the nervous system. We live in a period in which great strides are being made in preventive medicine. Although the greatest advance is being made in preventing zymotic diseases, yet good work is being done in other branches.

Infectious diseases are caused by the introduction of germs into the system, but the symptoms of the disease are caused by a chemical poison, *viz.*: a ptomaine which is produced in the body by the microorganism. Many diseases of the nervous system are likewise caused by a toxic agent in the blood; some suddenly, others insidiously, by the tissues being continually bathed with the toxic agent.

My object in writing this essay is to bring the subject before you, that you may be constantly on the alert to detect the toxic agent and to eliminate it, or prevent its further formation or introduction into the system before it shall have produced irreparable damage to the nervous system. In the past few years there has been considerable work done in this direction, although not all from the same standpoint, as our knowledge is still meagre and unsystematized. Brunton, in his volume entitled "Disorders of Digestion," which is made up of miscellaneous papers, treats of the subject of nervous disorders caused by poisons, formed during imperfect digestion, very pleasantly and scientifically. Dr. A. M. Brown has treated the subject of nervous disorders caused by toxic agents produced in the body, viz.: ptomaines, leucomaines, etc.; also does Sir William Aiken, in his little work entitled "The Animal Alkaloids, viz.: the Ptomaines, Leucomaines and Extractives in their Pathological Relations." In 1888 Drs. Vaughan and Novy wrote a work entitled "Ptomaines and Leucomaines," which embraced all of our exact knowledge on these subjects up to that date, including a bibliography of the same.

Dr. Thomas Buzzard, in the Harvarian Lectures for 1885, treats very fully of the toxic agents in the blood producing multiple neuritis, also does M. Allen Starr in the Middleton Goldsmith Lectures for 1887. Fothergill, in his work entitled "Vaso-Renal Change versus Bright's Disease," claims that chronic Bright's disease, instead of being simply a local affection, is a complex pathological condition, caused by an uric acid diathesis; that the uric acid circulating constantly in the blood produces an irritation of the vaso-motor centre, which in turn produces the structural changes of the heart, kidneys and blood-vessels.

Da Costa, in the Middleton Goldsmith Lectures for 1888, entitled "On the Relation of the Diseases of the Kidney, especially the Bright's Diseases, to Disease of the Heart," brings forth five hypotheses or theories as to the cause of said pathological changes; the first and second claiming that the cause of the organic trouble is impure blood, which causes a contraction of the arterioles, which in turn causes the organic changes in the heart and kidneys. The third and fourth theories claim substantially that the structural changes in the heart and kidneys are produced by an organic change in the coats of the arterioles, thereby diminishing their calibre and increasing the resistance to the flow of blood. The third and fourth theories are substantially the same as the first and second, only the former begin at a later stage of the same pathological process. Fothergill has shown pretty conclusively that the organic changes in the arterioles are produced by the increased blood pressure caused by a spasm of the arterioles, which is caused by blood laden with toxic matter

producing an irritation of the vaso-motor centre. The fifth view, which in its main features flows out of some researches made by Drs. Da Costa and Longstreet, is that the original lesion is situated in the nervous ganglia. It is probably there that the trophic centres of the heart, kidneys and blood-vessels are located, although Da Costa seems to differ from Fothergill in that the original seat of disease is in the nervous ganglia. The discrepancy is more apparent than real, for Da Costa says: "I would thus locate as most likely the original starting point of the alteration of the vessels and of the heart muscle, in the nervous ganglia, in the parts of the nervous system controlling the nutrition of these textures."

"What the ultimate cause of the lesion is cannot be stated, nor need we assume that one cause alone will determine it. It may be gout, it may be lithæmia, it may be rheumatism, it may be alcohol, it may be lead, it may be purely perverted nervous functions from worry, from strain or from anxiety. Any one of these causes may start that alteration in the ganglionic nervous system which leads to degeneration and to the formation of increased fibrous tissue, and subsequent atrophy, and with it also to derangement in the heart and in the muscular textures supplied by the affected ganglia and nerve filaments." Thus we see that although the first anatomical change occurs in the nervous centres, the ultimate cause (according to Da Costa) of such change, is either a toxic condition of the blood or perverted nervous function from worry, etc.

We are not satisfied in the present, as many seemed to have been in the past, in finding the structural changes that have taken place, but we search further and endeavor to find the causes of such changes, in hopes that we may remove the cause before irreparable change in structure has taken place.

It is difficult in the present state of our knowledge to properly classify the various disorders of the nervous system that are due to a toxic condition of the blood; but in the present paper I will classify them according to the location of the lesion, hoping thereby to facilitate the study of the subject. First commencing with the peripheral nerve, we have multiple neuritis, which is nearly always caused by a toxic condition of the blood.

Cases caused by toxic agents introduced into the body. The most common one by far is alcohol, and it is a singular fact that most cases of multiple neuritis due to alcohol occur in females. The other poisons that produce multiple neuritis when introduced into the blood are arsenic, lead, and probably bisulphide of carbon and illuminating gas.

*Second.* Neuritis in zymotic diseases. The poisons of zymotic diseases are very productive of multiple neuritis. Those that are known to produce it are the poisons of diphtheria, variola,

typhoid and typhus fevers, severe malarial fevers, dengue, beriberi, and I have seen one case that was caused by erysipelas, and another that followed erysipelas and rheumatism, so it was doubtful which was the cause of the neuritis.

*Third.* Other blood states that are productive of multiple neuritis are those incident to gout, rheumatism, syphilis, septicæmia and leprosy. I have seen some cases that were probably cases of mild multiple neuritis in lithæmia, although the symptoms were not well enough marked to make the diagnosis absolutely certain.

*Neuralgia.*—I take up this subject at this point as a matter of convenience, keeping in mind at the same time the fact that neuralgia is of central origin, and when dependent on a toxic condition of the blood it is caused by the toxic agent irritating the central terminations of the nerve fibres, *i. e.*, the nerve cells. The blood states that produce neuralgia are diabetes, gout, rheumatism, syphilis, typhoid fever, malaria, lithæmia, uræmia and the various toxic agents that are produced by disorders of digestion. Some cases of neuralgia that are due to disorders of digestion are reflex, but the large majority are undoubtedly toxic.

There is a class of cases in which there is numbness of the extremities, more particularly of the hands and forearms, in which there are no symptoms of organic disease. Some of these cases are without doubt toxic. They occur in uræmia, lithæmia and alcoholism. It probably occurs in other toxic states, but we have no exact knowledge in regard to the subject.

*Diseases of the Spine.*—Acute myelitis is sometimes caused by the poisons of variola, typhus and typhoid fevers, rheumatism and puerperal fever. It is doubtful if acute myelitis is ever caused by syphilis or alcoholism, but they each undoubtedly cause subacute myelitis.

*Chronic Myelitis.*—The only blood poisons that are known to produce chronic myelitis are syphilis, alcohol and lead.

*Acute Atrophic Paralysis.*—It is doubtful if this affection is ever caused by the blood state, although it sometimes follows scarlet fever and measles, and in older children and adults typhoid fever and ague.

*Acute Ascending Paralysis.*—This disease is caused by the poisons of small-pox, diphtheria, typhoid fever and syphilis. Spinal hæmorrhage is caused indirectly by the action of the poisons of syphilis and alcohol on the coats of the blood-vessels.

*Locomotor Ataxy.*—In this disease the only blood state that seems to have a causal relation in many cases is syphilis, and although about 70 per cent. of the cases of locomotor ataxy are caused by syphilis, it does not seem to be so much the blood state that causes the disease, but it is rather a degenerative sequel of syphilis than a true syphilitic disease. The lesion is not syphi-

litic in histological character and the disease is rarely influenced by antisyphilitic treatment. A few cases seem to be caused by rheumatism, typhoid fever and alcohol.

*Primary Spastic Paraplegia.*—Syphilis seems to be the cause of this disease in a few cases, as it does also of some other degenerative diseases of the spinal cord.

*Diseases of the Spinal Membrane.*—Acute internal meningitis is sometimes caused by the poisons of scarlet fever and typhoid fever, acute rheumatism and septicæmia. Chronic internal meningitis is sometimes caused by the poison of syphilis, also by alcohol. Spinal meningeal hæmorrhage is sometimes caused by the blood state, as in puerpura, and in the hæmorrhagic forms of some acute specific diseases.

*Cerebral Disorders.*—There is no part of the nervous system that is as susceptible to the influence of toxic agents as is the brain, and it is not to be wondered at when we consider its delicate and complex structure and the diversity and complexity of its functions. The abundance of the blood supply to the brain, which is necessary for its functional activity, renders it all the more susceptible to the influence of toxic agents. Our knowledge of the etiology of cerebral disorders is so imperfect that it is difficult to treat the subject systematically, but I will try and present the subject in as practical a manner as I can.

First, taking diseases of the membranes. Hæmatoma of the dura mater or internal hæmorrhagic pachymeningitis is sometimes caused by the septic blood of typhoid fever, small-pox, etc., and frequently by the prolonged use of alcohol. Purulent meningitis is always (so far as I know) a secondary disease. As Stumpell says: "We should therefore seek most carefully in every case of purulent meningitis at the bedside, and more particularly at the autopsy, to discover the way by which the pathogenic virus reaches the meninges." The toxic agent is sometimes the specific poison of the various zymotic diseases, as the septic material that is developed in the later stages of the malignant form of zymotic disorders, also the septic poison from various wounds, abscesses, ulcerative endocarditis, etc.

*Tubercular Meningitis.*—Most cases of tubercular meningitis are secondary to the lung trouble, and the septic material is probably carried to the pia mater through the medium of the blood. When the meningitis is primary the virus or bacillus is carried to the pia mater through the medium of the blood, but why the bacilli should attack the pia mater and not the lungs, or other tissues, we do not know, but the age of the patient seems to have some influence. Thrombosis of the cerebral sinuses is sometimes caused by the specific virus of severe zymotic diseases.

*Disturbance of Circulation in the Brain.*—In many cases of hyperæmia or anæmia of the brain

the blood is not always toxic, as there may be simply an excess or deficiency of some of its normal constituents. There are many toxic remedies that influence the circulation of the brain. Alcohol, nitro-glycerine, nitrite of amyl, small doses of opium and many other remedies increase the blood supply to the brain; some by increasing the heart's action, as in the case of alcohol; others by dilating the arterioles and capillaries, as is the case with nitrite of amyl. Ergot, the bromides, chloral hydrate, veratrum, gelseminum and some others diminish the blood supply to the brain. Ergot, for example, accomplishes the result by contracting the arterioles, while others, like veratrum, produce the result by their action on the heart. Alcohol is the most prolific cause of cerebral hyperæmia, and it seems to be caused also by the poison of most acute specific diseases, as well as general plethora.

We are all familiar with cases of cerebral hyperæmia in patients that have disordered digestion with constipation. In these cases the hyperæmia is probably caused by poisons formed during imperfect digestion and absorbed into the circulation.

Anæmia of the brain is caused by loss of blood, and general anæmia by many drugs and poisons that are introduced into the body, as well as some toxic agents that are formed in the system, viz.: an excess of urea and probably also a curara-like poison formed during imperfect digestion and studied by Brunton, also an atropia-like poison, and likewise peptones, ptomaines, etc.

*Cerebral Hæmorrhage.*—A healthy artery probably never ruptures from blood pressure. Some pathological changes in the coats of the arteries are necessary as a predisposing cause; the most common change being miliary aneurism. The most prolific causes of the pathological changes in the coats of the arteries are alcohol and the poisons of gout, viz.: uric acid, also Bright's disease and the virus of syphilis. Thrombosis is frequently caused by syphilis.

*Tumors.*—Syphilitic and tubercular tumors are caused by the virus of their respective diseases.

*Insanity.*—There are a few forms of insanity that are caused by toxic agents, viz.: alcoholic insanity, syphilitic dementia and saturnine insanity. Syphilis and alcohol also play an important part in the production of many cases of parietic dementia.

*Convulsions.*—Although there are many toxic agents that will produce convulsions, those produced by an excess of urea are by far the most important—whether they occur in the puerperal state or not.

*Neurasthenia.*—Neurasthenics form a large class of our patients, and we are apt to think that all cases are caused by overwork or worry, and not look farther for a cause; but there is a large class of patients in the cities and larger towns of seden-

tary habits that are not overworked and that are well nourished. They go to their physician, and he says, "You are run down;" and he prescribes a tonic. The patient returns soon and is no better. Perhaps you prescribe another tonic and he returns again without any improvement, and then you tell him that he must leave his business and go into the country for a rest. While in the country he takes long tramps, fishing or hunting, or climbing mountains sightseeing, thereby getting more exercise in a week than he would in a month at home. In two or three weeks the patient feels strong and vigorous; his spirits are buoyant, and he feels that the change of air has produced the cure; but how sadly is he disappointed when, two or three weeks after his return to his counting room or office, he finds that he is as bad as ever. How do we account for this condition of things? It is simply this: he is not overworked, but he is overfed. He takes no exercise, and he keeps up his appetite with relishes, condiments and perhaps wine, so that he is enabled to take into his stomach two or three times as much as the laborer that works on the highway. Thus we see that the depression is caused by an excess of food.

The patient takes into his stomach more than he can assimilate, and the products of imperfect digestion are absorbed into the circulation, where they act as poisons to the nervous system. We can compare the patient to a stove. We put on the fire fresh coal before we remove the burned out waste material from below; now we find that instead of our fire burning briskly, it is more deadened and useless than before. If we had removed the products of waste by shaking it down the fire would soon have brightened up; so it is with our patient.

I have omitted some affections that are sometimes caused by a toxic agent in the blood—but, fearing that I will weary your patience, I will conclude this paper with the subject of headaches.

There have been many attempts to classify headaches; some systems are very complicated, others very simple, but all are open to objections, and no system, in the present state of our knowledge, can be faultless.

One author simply divides them into two classes, viz.: anæmic and hyperæmic. He claims that this classification tends to simplify treatment, but I think it tends to mislead one, as the following will illustrate:

Mrs. S., æt. 35 years, was sent to me by Dr. P. She complained of severe and persistent headaches and nothing else. Dr. P. made an ophthalmoscopic examination and he found optic disc anæmic.

The arteries seemed wiry, and I concluded that it was a case of anæmic headache due to spasm of the arteries, and put the patient on nitro-glycerine. It gave her relief, but the pain would return as soon as the effects of the remedy wore

off. I ordered her to save me a sample of her urine. I found that it was loaded with lithates. I then put her on a course of blue pills, saline purgatives and alkaline diuretics, and ordered her to abstain from eating meat. She made a speedy recovery.

Thus we see that we had an anæmic headache that was in fact a toxic one. The most common toxic headache is probably produced by alcohol, with the possible exception of the digestive headache. Although some digestive headaches are undoubtedly reflex, they are nearly all toxic.

There are a great many toxic agents that are capable of producing headaches. Among the most important are alcohol and the various narcotics—lead, impure air, various gases, viz.: illuminating gas, carbonic oxide, sulphuretted hydrogen, etc. There is the poison of various zymotic diseases, of gout, rheumatism, diabetes, Bright's disease; and there is the uræmic headache and the headache of lithæmia. It therefore behooves us in every case of nervous disease not only to locate the lesion (if the disease be organic), but to examine carefully and ascertain if there is any toxic agent that is producing the trouble.

#### SOME CASES OF INFLAMMATION AND ATROPHY OF THE OPTIC NERVE WITH SPECIAL REFERENCE TO ETIOLOGY AND PROGNOSIS.

*Read in the Section of Ophthalmology, at the Fortieth Annual Meeting of the American Medical Association, June, 1889.*

BY J. L. THOMPSON, M.D.,  
OF INDIANAPOLIS, IND.

Of all diseases of the eye and its appendages, none are more perplexing to us as regards etiology and prognosis than are those of the optic nerve. Inflammations and atrophies of said nerve are easily diagnosticated, but when asked the question, what caused this or that inflammation or atrophy? or, what will be the result? then do we often find ourselves unable to answer. Some of them may be read as easily as an open book while others upon the contrary baffle us at every turn, and though every opportunity may be offered by the patient objectively and subjectively, still sphinx-like the cause forever remains to us a sealed scroll.

Take for example the two cases which follow:

*Case 1.*—J. D., aged 38, occupation baggage master, a fine looking man the picture of health, who came to see me about his failing sight which was found at that time to equal  $\frac{2}{10}$  in either eye, the ophthalmoscope revealed well marked commencing atrophy of the discs, which contained fewer nutrient vessels than normal. A most careful examination of this patient, objectively and subjectively, failed to give any clue as to the cause of the change above mentioned. He never

had syphilis, rheumatism, kidney or heart trouble, spinal disease of any kind, nor was he troubled with any affection attributable to malaria. He used neither alcoholic beverages, nor tobacco in any form. I put him upon increasing doses of the iodides for some weeks, but as no good results followed, hypodermic injections of strychnia were used, beginning with small and ending with large doses, but in spite of this, his vision slowly but steadily decreased in acuity until it fell to  $\frac{1}{200}$ , where it remained for 9 months, when I lost sight of him, he having left the city.

*Case 2.*—C. S., aged 23 years but looks much younger; indeed he has the appearance of a boy; height 4 feet 11 inches, weight 90 pounds. His sight commenced failing in the left eye sixteen months ago while engaged in drafting in an architect's office in Minneapolis, Minn. He soon consulted an oculist of that city, who diagnosed commencing atrophy of the left optic nerve. His vision slowly became worse, until about three months ago when he could not see any object with it. Again did he consult the oculist, when complete atrophy of the nerve was found to have taken place; but no cause for it could be discovered. Another able oculist was called on, who found as did the other gentleman, nor could he arrive at any definite conclusion as to its cause, nor could either of them tell the young man or his relatives as to the probable result in the other eye; they feared however that it would be attacked also. He called on me June 2nd, 1889, when I found as did they, white atrophy of the left optic nerve with vision equal 0, and in the right the disc looks a trifle whiter than normal, vision equals  $\frac{1}{10}$  nearly (misses two letters in the line). The eyes looked natural externally except the appearance of a slight insufficiency of the internal recti muscles; the pupils are of equal size, but when the right eye is closed by holding a handkerchief over it the left pupil does not respond to the brightest light. I have questioned him and his sisters in every way in order to arrive at its probable cause, but only get the following history: Father and mother both dead, the former from gall stone, the latter from consumption. His sister says "Carl has had vomiting spells at different times for at least thirteen years. They have never seemed to occur at any special time of the day, and seldom have they occurred when we could feel that there was a cause for them, nor have they come on at regular intervals. They usually begin with a dull headache soon followed by vomiting, which continues (during the severe attacks) for hours and sometimes days. The vomiting is usually followed by sleep. He vomits great quantities of mucus and bile. The intervals between vomiting are not regular, sometimes not more than fifteen minutes apart, again a half an hour or an hour or more. He always

looks very pale about the mouth and nose, the latter having a pinched appearance. We feel that these attacks have become less frequent and less severe. In the last three years I do not think he has had more than four attacks, during which the vomiting has lasted a day and night, yet he has had others less severe when he looks pale, is sleepy and has no appetite."

It will be seen from the above that his sight did not begin to fail until after these paroxysms of vomiting had become less severe. He never had any symptoms of malarial poisoning, no spinal symptoms, nothing to indicate tumor of the brain. His urine is normal.

*Remarks:* The two cases given above are typical of many similar ones which we all very frequently meet with. Doubtless, there is not a person present of ten years' experience in this specialty, who has not had at least forty similar cases. I have watched many such, where both nerves have failed; as in case No. 1, and though the cause forever remains obscure during life, and doubtless even an autopsy would give negative results, the prognosis in such cases is that though they may remain stationary they never improve. As regards the prognosis in case No. 2, the question usually asked is, am I liable to become blind in the other eye? Unfortunately, the physician first consulted over a year ago, does not give the exact acuity of vision, he simply recorded vision in right eye normal. If it was  $\frac{2}{20}$  a decrease has already taken place, as it now only equals  $\frac{1}{30}$ . It is more than likely though, that the young man's acuity of vision never was greater than  $\frac{1}{30}$ , or possibly, when the left eye failed the right participated and has remained stationary since. From many similar cases which I now remember having seen my prognosis would lean to the belief that as the left went so rapidly, and an interval of over three months having elapsed, in which the young man has noticed no change in the other eye, the cause which led to the atrophy has expanded its force on the left and has ceased to exist.

*Case 3.*—Mrs. H., aged 28, mother of two children, the youngest two years old, was attacked with a pernicious intermittent fever on the 21st of August, 1878, she became stone blind immediately. I saw her in consultation with her physician seven days afterward and made the following record: Pupils widely dilated and fixed, eyes have the peculiar expression of one totally blind, balls move in every direction (they were said to have been fixed for several days after the attack), cannot perceive the brightest light. Phosphines not produced when pressure is made over the region back of the ora-serrata, vessels of discs and retinae look as small as threads. The supposition being that there was an effusion of serum at the base of the brain, she was treated with counter-irritants on the back of the neck

and given increasing doses of the iodide of sodium and tonics. She began to discern light in about two weeks, and in two months large objects, but relapsed and remained blind for six months. My second examination found the optic discs almost as white as glistening pearl, with no nutrient vessels in them and the central vessels small as threads. For several years she could only distinguish between light and darkness, but, after six years her vision began to improve and in the spring of 1888, ten years after she was first attacked, her vision equalled  $\frac{2}{20}$ , and she can now drive her phaeton over the familiar roads. Several other cases of amaurosis have I seen, which were caused by severe forms of intermittent fever, but this is the only one which improved after so severe and well marked atrophy of the discs.

*Case 4.*—A young man aged 18 years became suddenly blind while playing violently at base ball. He called on me a few days afterward when neuro-retinitis with terribly choked discs, and hæmorrhagic patches over the fundus of each were manifest. He could not see a ray of light with either eye. He was leeches very freely on the temples, and salines were administered. One eye remained permanently blind, with the snow white disc; but, after a few months the other so improved as to enable him to teach a country school, and at my last examination, five years subsequently, his vision equalled simple perception of light right and  $\frac{2}{30}$  left.

*Case 5.*—Mrs. P. B., aged 27, mother of three children, the youngest one year, then nursing. She brought me a letter from her physician who stated that he was treating her for sub-involution of the uterus, when she took a violent headache and in three days became entirely blind. My examination showed that she could not see a ray of light, the pupils were dilated to the utmost, and unmovable, T+1<sub>2</sub> each eye, the discs were fearfully choked, arteries almost invisible, veins very tortuous, and only to be seen in places. She had a very thick short neck and flushed face, with ears as red as a boiled lobster. Salines were given, leeches were applied every few days, the child was weaned, and increasing large doses of the iodides with bromides were given. She began to see the light in three days, then large objects. They steadily improved until her last visit, three months after the last attack, when vision equalled  $\frac{2}{30}$  either eye.

The two cases above were of the congestive type, in which the prognosis is usually highly favorable.

*Case 6.*—Mr. A. McC., aged 23 years, was sent to me in February, 1883, with a letter from his physician saying: I was called to see him last August when he had a high degree of fever, headache and vomiting, which lasted five days; his temperature was 103°; has had three similar at-

tacks since and has just recovered from one; have given him bromides, strychnia, etc. On questioning the patient I learned that he had been treated by another doctor for a chancre and buboes long before the physician who sent him to me had seen him. I found double optic neuritis with choked discs and dilated pupils, with vision equal 0. I wrote to his physician suggesting that he treat him for basilar meningitis, with very large doses of the iodides. He became better but I never learned what the acuity of vision equalled.

*Case 7.*—Miss S. S. D., aged 22, a delicate refined looking lady teacher in a seminary, brought to me by her physician who supposed she had hysteria; he told me that he did not think it necessary that I should see her, but on the opportunity of her friends had brought her, that he had examined her eyes with the ophthalmoscope, had found no structural trouble, and had so informed her, and also predicted that as soon as she gained a little more strength she could resume her school work. He informed me that she had been taken quite seriously at first with a very intense and persistent headache and vomiting, her temperature had been very high, her appetite very poor and she had become very nervous, but as she became better the hysteric symptoms came upon her. I found the pupils dilated and rather sluggish; made drawings of each fundus while the physician looked over my shoulder. There was well marked inflammation of each optic nerve, which was serrated and extended far beyond its normal boundry; the vessels could only be seen in places, arteries thread-like, veins tortuous and sacculated in places; there was well marked effusion between the sheathes of the nerve. It was as plain a case of basilar meningitis as ever was seen. She was put upon the iodides and tonics, became better, went home to her parents in Vermont, but, as I have since learned, died six months subsequently, from what disease I have not learned.

The two cases reported above were very similar in many particulars. From the colored drawings which accompany my records on my case book, one can scarcely see a particle of difference, and yet the causes which brought these conditions about were widely dissimilar. In the one, case No. 6, syphilis was the important factor, while in the other which took place in a refined delicate lady teacher, doubtless undue mental strain with loss of rest was the cause. The prognosis in case 6 was rather favorable, while in case 7 it was much more grave.

*Case 8.*—Anna F., aged twelve years, brought to me by her mother on April 17th, 1884, with a letter from her physician, had suffered with terrible headaches for six months, during which time she had vomited very hard every Sunday morning; two weeks before they consulted me she had convulsions, four during one night; was

unconscious for one day, then became quite blind. In two days her sight became better but was followed by paralysis of the left side of the face, and ringing in both ears. My examination found pupils slightly dilated but responsive to light, eyeballs straight and movable in every direction, vision equalled  $\frac{2}{10}$  right and  $\frac{2}{10}$  left. The ophthalmoscope revealed well marked neuro-retinitis both eyes and choked discs, with effusion beneath the sheathes of the nerves. A letter was given to her physician who placed her upon the iodides, increasing doses. I saw her again in one month and found the fundus of each eye looking much better, vision also had improved to  $\frac{3}{10}$  right and  $\frac{2}{10}$  left eye. I learned afterward that she soon became worse, when they changed their physician for one who was both physician and specialist in the eye. She died September 30th, when her former physician tried to get consent to a post mortem examination, but, through the influence of the last physician called it was refused. It was evidently one of tumor of the brain, this had been my diagnosis, and as the prognosis was gloomy and imparted to the parents as such, probably it brought about a change of doctors.

*Case 9.*—D. W. B., aged 12, was also sent by her physician on account of her failing sight and double vision occasionally. Her health had not been good since an attack of typhoid fever nearly two years before. She had been subject also to an occasional epistaxis since she was four years old, but lately had complained of most atrocious headaches. My examination resulted as follows. Eyes equally well opened, movement of eyeballs complete in every direction except that they behaved as do eyes with an insufficiency of the internal recti, which on the use of prisms proved to be the case. Pupils natural and mobile, vision equals  $\frac{2}{10}$  right and  $\frac{2}{10}$  left, apparently emmetropic. With ophthalmoscope I found a double optic neuritis with slightly choked discs. I at once wrote to her physician that I feared we had brain tumor to deal with and had her put on the iodides as in the preceding case. She improved for a while but as she fancied that the medicine caused sickness to the stomach it was discontinued, but still she continued to vomit every morning about 4:00 o'clock for about three weeks after the medicine had been stopped. She then improved in appearance, increased in weight and her sight became better. Ophthalmoscopic examination showed that the optic discs had become flatter and less evidence of inflammation was manifest, indeed they looked almost natural. On April 5th, her mother informed me that she had a chill and sinking spell, with temporary loss of power in the right arm and side, this soon passed off but the vomiting again came on in the morning as did the headaches. Again did she improve and was taken on a visit to relatives in

Kentucky. Still she never felt quite well. "O mother," she would say, "I wish people would not ask me if my head hurts me? it always hurts, but not enough to keep me from reading or playing." I saw her but twice after April 6th, when I noticed a well marked prominence of the left eye ball, though not as much as is met with in the milder cases of Graves' disease. Her vision, however was much improved and the discs looked almost natural. Her subsequent history as given me by her mother after her death is, that she played and read as usual until six weeks before her last sickness, when she had an attack resembling erysipelas, red puffed and shining skin, which her physician soon relieved with a lead lotion. She then became apparently better than ever. Had a ravenous appetite until May 1st when the vomiting and headache returned worse than before. She soon lost all use of herself and could not even be propped up in the bed. Her physician found her completely paralyzed, with the left eye much protruded and a purulent discharge from both. She sank very rapidly and died. I was invited to the post mortem which was made 20 hours after death. Her eyes then looked quite natural, with not the slightest protrusion of either. On removing the calvaria the membranes were very much congested as was the surface of the brain. About five ounces of serum escaped during the removal of the brain which was carefully sliced away. Nothing of note appeared until the cerebellum was reached, when we found the entire left lobe occupied by a tumor of much greater density than the brain substance. It was hardened and sent to Dr. H. Knapp of New York for a microscopic examination. Dr. J. E. Weeks, a very skilful microscopist, said of it: "It shows the structure of gliosarcoma. The fatty changes in the interior of the tumor are quite extensive. There is also extensive round cell infiltration into the surrounding tissues."

*Remarks:* In the two cases just reported there is a remarkable coincidence. Both were young girls aged 12 years. Both had symptoms of meningitis as well as of brain tumor. One point of interest connected with these growths is that the patient often becomes much better, with greatly increased acuity of vision, and almost complete disappearance of inflammation of the optic nerve, so much, at times as to almost cause one to doubt the correctness of his diagnosis. Another point worthy of mention is that though one is confident that he has a tumor to deal with, yet to locate it during life is usually impossible. Who would have supposed that after a double optic neuritis with protrusion of the left eye that the tumor was as far back as the left lobe of the cerebellum? Again; the nature of the tumor cannot be arrived at during life, consequently we cannot be positive that death will certainly result, as there are

many cases on record where every symptom of tumor was manifest, and yet under the use of the iodides they have disappeared. If my allotted time permitted I should add cases of inflammation and atrophy of the nerve from Bright's disease, alcoholic and tobacco poisoning, and pigmentary degeneration, but the prognosis in these is by no means uncertain. In the first, Bright's disease, all of my patients have died in from one month to two years, except when the disease occurred in the puerperal condition. Several of these have died, some have recovered perfect vision, and one remains entirely blind with white atrophy of the papillæ. In alcoholic and tobacco poisoning we may promise much, if the patient will abandon the poison before atrophy has set in, but if that has already commenced I have never seen the slightest improvement in vision follow. In pigmentary degeneration of the retina either in the congenital or acquired form, atrophy of the nerve accompanying it has never, so far as I have seen, improved in the least degree, but on the contrary has gradually become worse. From my observations in several hundreds of cases of inflammation and atrophy of the optic nerve during the last eighteen years, I have been led to the following conclusions:

*First.* Progressive atrophy with no evidences of former inflammation, rarely gives any clue to its etiology. In such cases the prognosis is, that vision rarely improves. If it occurs in but one eye which quickly becomes blind and after an interval of several months no sign of failure in the acuity of vision takes place, then the prognosis is favorable as to the second eye.

*Second.* In atrophies of the nerve following pernicious intermittent fever, though vision has been almost nil for years, it often improves very much when least expected.

*Third.* Inflammations of the optic nerve resulting from violent exercise, disturbances in menstruation, etc., occurring in plethoric persons admit of a very favorable prognosis.

*Fourth.* Atrophies occurring in very anæmic patients usually permanently impair or destroy vision.

*Fifth.* Where inflammation of the nerve is caused by meningitis and that is of syphilitic origin the prognosis is highly favorable; but when said meningitis is of other origin the prognosis is gloomy as to sight and life.

*Sixth.* Inflammations of the optic disc caused by brain tumors often change so in appearance, and such improvement takes place in the patient, owing to subsidence of meningeal inflammation, effusion and other modifying causes, that one is liable in some cases to doubt the correctness of his diagnosis or to modify his views as to the prognosis; but death is the result with few exceptions.

*Seventh.* Inflammation of the optic nerve and

retina occurring in the course of Bright's disease, means death in from one month to two years. I have seen many cases and none have survived the last mentioned period, except pregnant women; some of these have died. One (in whom premature labor was brought on) has perfect vision and one where it was not produced is stone blind.

*Eighth.* Atrophy of the optic nerve following long continued abuse of alcohol and tobacco combined calls for an unfavorable prognosis as regards vision. But where those poisons are given up before atrophy sets in, even though the sight is but  $\frac{1}{2}$  to  $\frac{3}{4}$ , perfect restoration of vision usually takes place, not by the "tapering off" method, but by the sudden discontinuance.

*Ninth.* Atrophy occurring during the process of retinitis pigmentosa, either congenital or acquired, offers nothing favorable as to prognosis.

## INTERNAL EAR DEAFNESS, ILLUSTRATED.

*Read in the Section of Laryngology and Otology, at the Fortieth Annual Meeting of the American Medical Association, June, 1889.*

BY J. G. CARPENTER, M.D.,  
STANFORD, KY.

The theme of labyrinthian deafness is one of very great interest, because it is so often incurable, and is generally secondary to, or the sequel of many affections; and to cure the disease, the ailment on which it depends must be cured, the pathological lesions removed, before irreparable structural changes have taken place in the inner ear. The premises will be made in this paper that internal ear disease is dependent more often on middle ear disease, and the latter, most frequently dependent on chronic nasopharyngeal catarrh, for the predisposing cause, and acute congestion or acute inflammation of the upper respiratory tract and aural apparatus, for the exciting cause; making due allowance, of course, for other etiological factors. Experience and observation teach the writer that doubtless chronic nasopharyngeal catarrh is present in the majority of such cases; is the most frequent of all other causes; and, if the previous history of these cases was ascertained before the labyrinthian deafness supervened, chronic catarrh of the nasopharyngeal passages would be found the starting point.

Mr. —, age 35 years, previous health and family history good, came to be treated for slight deafness. Upon rhinoscopic and aural examination it was ascertained that he had chronic nasopharyngitis with catarrh of the Eustachian tubes and tympani; audition in right ear,  $\frac{1}{4}$ , left ear  $\frac{3}{4}$ ; the membranæ tympanorum more or less opaque; the light spot diminishes in the right more than in the left. The turbinated pro-

cesses and septum hypertrophied. Patient admits that the deafness supervened a year or two after the catarrh of the nasal chambers. The disease improved rapidly from the local use of warm, mild, soothing, astringent, non-irritant sprays, and inflation of the Eustachian tubes with warm air (using Rumbold's warm air inflator) daily for a week. The chronic catarrh improved rapidly, and the deafness was relieved. In a few days an acute catarrh of the upper air passages occurred and extended into the middle ear; the deafness also returned. The acute attack was soon checked, and local treatment continued, the Eustachian tubes being inflated daily for several days. But the hearing in the right ear instead of increasing as before got worse, and within two weeks from the acute attack deafness was complete. No aerial or bone conduction of the vibrations of the tuning fork could be discerned. Upon close interrogation, patient admitted that during a sojourn in the city, several weeks previous, he contracted what the physician called chancre, but that it had healed. On examination by palpation and ocular inspection a chancre and a typical case of syphilis was diagnosticated. Patient was placed on anti-syphilitic treatment; in three weeks from the commencement of the latter, tuning fork could be heard; in six weeks the labyrinthian deafness was cured, and syphilis eventually eradicated. In addition to the congestion and effusion from the acute catarrh in the aural apparatus there was also a syphilitic exudation, no doubt, pressing on the auditory nerve suspending its functions temporarily, and which was relieved and cured by the anti-syphilitic treatment.

W. S. M., age 40 years, has good health, and an excellent family history. In the month of June had intermittent fever for which he took, of his own accord, fifty grains of quinine in twenty-four hours. He was sponged freely with cold water during the pyrexia, and after the subsidence of fever the bed was left during the night between two open windows; from the exposure to the draught an acute rhinopharyngitis, with acute otitis media, and internal ear deafness of right ear developed. Neither the tick of a watch, loud conversation, nor the tuning-fork could be heard. Bromide of potassium, gr. xxx, and the iodide, gr. v, were given three times a day for a week. The former, when given with quinine, prevents the tinnitus aurium, throbbing, and headache, if the latter, and was given to arrest congestion; the iodide was given to cause absorption of any effusion in the labyrinth. The external ear was syringed with water as hot as could be tolerated every half hour, or hour, to check pain and inflammation. The nasopharyngeal chambers were sprayed with warm, soothing, mild, non-irritant, astringent medicines, with vaseline for the base; one or two drachms were

used at each treatment daily for five days. The third treatment was supplemented by inflation of the Eustachian tube with Rumbold's warm air inflator, as were the subsequent treatments. After the fifth day local treatment was given every other day for a week. By the seventh day the acute attack had subsided, and by the tenth day the internal ear deafness was cured. The potash mixture was discontinued and patient directed to avoid exposure and employ daily massage of the integument.

Did the fifty grains of quinine administered in twenty-four hours cause congestion and effusion in the labyrinth and internal ear deafness? or was it the acute inflammation of the nasal chambers extending by continuity of tissue from the Eustachian tube and middle ear to the inner ear? The writer believes that both were important factors directly concerned in the production of the labyrinthian deafness. First, because quinine is known to cause congestion and effusion within the membranous labyrinth; not only this, but it may congest the tympanic cavity and auditory canal, as is proven by the *tiinitus aurium*, headache, dizziness, and impairment of hearing, which follow large and repeated doses of quinine; the latter in large doses has been known to cause "severe otitis." Patients who have taken large doses at short intervals have often said to the writer: "Last evening I had neuralgia in my ear and I awoke in the night from a popping noise in my ear; I ascertained that there was a discharge from it, and as soon as the discharge began the pain left." On the auroscopic examination the drum-head would be found perforated and a serous, or serosanguinolent, otorrhœa present, and this otitis has occurred independently of any cold. Page 155, Roosa's "Treatise on Diseases of the Ear" gives a case illustrating quinine as the important factor in the production of "severe otitis." At page 504 he states; "I have been convinced by experience that it (quinine) has a peculiar power of congesting the auditory apparatus." But at page 157 in addition to proving that quinine caused the "severe otitis," he has not disproved that from time to time coincident with taking the large doses of quinine that there was not also a subacute rhino-pharyngitis ingrafted upon the chronic, extending by continuity of tissue to the auditory apparatus, and equally important, if not more important, than the quinine in causing the "severe otitis." At page 155 Dr. Roosa states the laryngeal inflammation was followed by chronic naso-pharyngeal catarrh. On this point the cart seems to have been placed before the horse, or the shadow has been taken for the object *per se*, for the laryngeal and aural affections had their origin in the naso-pharyngeal chambers, and the former were but the sequelæ of the latter, aggravated by acute or subacute inflammation. But at the time this case of Dr. Roosa's

was published the millenium of rhinology had not come to pass. Now old things have passed away and we no longer see through a glass darkly; it is true that a bird's-eye view had been taken of the rhinal passages, but the primary, clinical, anatomical, neurological, and pathological, importance they now possess was not accorded them until within the last decade.

By treating locally the naso-pharyngeal chambers the labyrinthian deafness and middle ear complications subsided, *pari passu*, as the acute inflammation of the upper respiratory tract did, proving almost conclusively that the disease was originally in the naso-pharyngeal chambers. It can be easily seen how by extension of inflammation by continuity of tissue from the rhinal passages through the Eustachian tubes and tympana the labyriuths may become involved; either an effusion in the tympanum causing pressure inward of the inner tympanic walls, or membrane of fenestra ovalis and membrana tympani secundaria, and involve the auditory nerve in the vestibule and cochlea; or the congestion and effusion may be so great as to equally involve both the middle and inner ear and produce labyrinthian deafness.

Miss —, age 23 years, health feeble, has never been strong and healthy since an attack of scarlet fever in childhood, and from this period she has had throat disease. Subjective examination presents the following: patient is anæmic, slightly dyspeptic, despondent, irritable, has more or less constant occipital or frontal headache, has ringing of bells in the ears, is weak and tottering, has cold hands and feet, blank, desponding expression, skin harsh and dry, has laryngeal irritation and discomfort, mouth breathing, great inclination to swallow, tongue coated white, sense of smell impaired, bad taste in the mouth, more or less hawking and expectoration, cries a great deal, is subject to neuralgia; is, in fact, quite neurasthenic. On rhinoscopic and auroscopic examination the accompanying described states were present, chronic, hypertrophic naso-pharyngeal catarrh; Eustachian and tympanic catarrh; the drum heads opaque, the left more than the right, the light spots diminished; audition of both ears was nil, neither the watch, loud conversation, nor the tuning fork could be heard; there was complete inner ear deafness. When the impaired hearing was confined to the middle ears the hearing would improve in dry, warm weather, and get worse in damp or wet weather. Patient is quite subject to colds, in fact is seldom free from one before another begins; really has the so-called catarrhal diathesis.

Constitutional treatment consisted of ferruginous and nerve tonics internally; inunctions of vaseline and massage externally daily, as the hot bath was enervating and added to the discomfort and suffering of the patient. A cold

bath or a tepid one caused repeated attacks of subacute catarrh, or cold in the upper respiratory and aural passages; consequently vaseline inunctions and massage were really in demand and necessary to cleanse and stimulate the skin, and restore the latter and the circulation to their former natural state, and to fortify the body against future colds.

Local treatment consisted of warm, mild, soothing, astringent and non-irritant applications in the form of a spray, with vaseline,  $\mathfrak{z}\text{j}$ , for its base, combined with oil of eucalyptus,  $\text{gtts. v}$ , Kennedy's pinus canadensis,  $\text{gtts. xv}$  and carbolic acid,  $\text{grs. ij}$ , made into a mass, and one or two drachms of this sprayed into the naso-pharyngeal passages, preceded when necessary by the cleansing lotion of Dobell, or listerine and glycerine each  $\mathfrak{z}\text{j}$ , dose one teaspoonful with one of chloride of sodium in a pint of water, and sprayed warm; (for twenty days.) Fifteen days after the commencement of treatment, when the inflammation was greatly reduced, as were also the swelling and infiltration, the Eustachian tubes and middle ears were inflated with Rumbold's warm air inflator, charged with distilled water  $\text{Oss. tr}$ , iodine,  $\mathfrak{z}\text{j}$ , daily, after the cleansing mixture and vaseline compound had been used. This treatment was used for inflation because the air in the Eustachian tubes and tympana is believed to be in a rarefied state normally. Second, because from the congestion and infiltration of their lining, warm rarefied air is much more likely to permeate the Eustachian tubes than cold air from Politzer's method, the Eustachian catheter, or from Pomeroy's faucial catheter. Third, neither inflation nor catheterization of the Eustachian tubes should be resorted to until the congestion and chronic inflammation of the naso-pharyngeal chambers is reduced to a minimum, and foreign bodies or occlusion have been removed. By thus checking the inflammatory process in the upper air passages the ear affections consequent upon it are arrested and cured much more easily, and return to their normal state and function *pari passu* with the former. After the twentieth treatment locally of the chronic rhino-pharyngitis, and fifth inflation, the tuning fork was heard by bone conduction in the right ear, and after the twenty-fifth treatment and tenth inflation, in the left ear. After the thirtieth treatment hearing returned strong enough for the patient to hear the hammering noise of the carpenters on the building adjacent to the office, and to hear the town clock strike, which was about thirty yards away. From this time the treatment was continued every other day for two weeks, when Miss — could hear the aerial vibrations of the tuning fork, the watch eighteen inches away in right and six inches in left ear, and hear spoken and whispered conversation. And while the chronic naso-pharyngeal catarrh was not cured,

entirely, the accompanying symptoms had been relieved, life has been made more pleasant and comfortable, but to permanently cure the former the patient should take some treatment during the fall or spring, or both, to prevent an aggravation of the disease and effect a permanent cure. The physician places the upper respiratory tract in the most favorable condition aseptically and antiseptically for recovery, and through this *vis-medicatrix naturæ* the disease is cured by the mucous and submucous tissues becoming regenerated or growing into former natural state.

Patient was satisfied with results, both anæmia and neurasthenia having subsided. This case, in truth, was an extreme one, and shows conclusively what can be successfully done for suffering humanity. When the premises are right, and one goes right, one is sure to end right.

The cause of the internal ear deafness was primarily in the naso-pharyngeal chambers, viz., chronic naso-pharyngeal catarrh, and it having continuously and slowly invaded the Eustachian tubes and middle ears, producing middle ear deafness; and, having caused chronic irritation or congestion of the labyrinth, it was very easy on the supervention of an acute inflammation of the upper air passages and auditory apparatus to have tympanic and labyrinthian deafness. The latter, either from traction on the ossicula audita by effusion, on the auditory nerve, or from congestion and effusion of the labyrinth.

Rhinologically considered, in the future not only will there be more tympanic disease and deafness cured, but also, labyrinthian disease and deafness; and the writer is convinced from the successful issue in these and other cases observed that the "royal road" to the successful treatment of middle and internal ear disease is in the majority of cases in and through the naso-pharyngeal passages, and before serious structural lesions have taken place in the former.

It is very easy to account for the diverse affections following catarrhal inflammation of the upper air passages, when the physiological, anatomical, lymphatic, neurological and clinical relations of the parts are considered. The meninges and base of the brain are in close proximity to the catarrhal mucous membrane and many blood vessels that the latter supply also supply the former either directly or indirectly. The same is true in regard to the distribution of the cranial nerves. They communicate with various ganglia and proximate and remote organs, and convey irritations directly or reflexly to different parts of the body. With what facility then, when pain, irritation, or inflammation is produced in the terminal filaments of a nerve supplying the mucous membrane of the upper air passages can it be transmitted to distant organs or membranes. It is equally easy to have an irritation or congestions of the brain follow chronic catarrhal in-

flammation of the upper air passages, as tympanic or labyrinthian deafness or laryngitis.

Physiologically the nose warms the respired air, frees it from foreign material before passing into the lungs, protects the air passages, and through the sense of smell warns its possessor of the presence of pleasant or irritating gases, or noxious substances, and its lining is the first part of the respiratory tract to become irritated and chronically congested, or inflamed, and extending by continuity of tissue to the pharynx, tonsils, larynx, trachea, eye, frontal, ethmoidal and sphenoidal sinuses, and to the antrum, Eustachian tubes, and aural apparatus.

## THE CLINIC.

### CLINICAL LECTURE DELIVERED NOVEMBER 13, 1889, AT THE HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

BY W. GOODELL, M.D.,  
PROFESSOR OF GYNECOLOGY.  
[Reported for THE JOURNAL.]

#### ABDOMINAL TUMOR, WITH ADHESIONS.

*Gentlemen:* I must do a little gold beating to-day. By this I mean, that as a small piece of gold is beaten out into a large leaf, so I shall have to spin out what I have to say to-day out of a very small text. I have comparatively little material to bring before you and no operations to fill up the hour. To begin our gold beating:—Day before yesterday, I received from a physician a note, telling me that there was in a small alley in the suburbs of this city, a very poor woman with a uterine tumor, and asking me to get her into the hospital. Therefore, yesterday the ambulance was sent for her and she was brought into the female ward. This morning I bring her before you without having seen her, in order that you may learn how to make a diagnosis.

She has a large and solid tumor in the right side of the abdomen, which extends very nearly to the liver, and is almost immovable by adhesions. This you can plainly see as I expose her abdomen. She says that she is fifty-six years old and the mother of thirteen children, that her menses ceased one year ago, that this tumor has existed for several years, and that it has been getting larger and larger since her menopause. She suffers a great deal of pain from this tumor, and has now a frequent pulse and high temperature. Her tongue is dry and red, and she has the hebetude and dulness of sense, due clearly to blood poisoning, probably from the presence of pus somewhere.

I see upon her abdomen what I at first took to

be the scar of a burn; but she tells me they came from a child-bearing and now, upon observing them more closely, I find that she is right. They are lineæ albicantes, old ones stretched open from previous pregnancies and, therefore, white and glistening; not purple, as they would be, if they were of recent origin.

The tumor presents the feature of a fibroid of the womb, but constant pain is rarely associated with such a growth, when it lies above the pelvis, then again septic symptoms should not be present. It is clearly not a cyst, for it is too hard and nodulous. Can it be a malignant growth? a sarcoma or a carcinoma? The latter could not have lasted so long as six years, nor could a sarcoma, unless the growth were first benign, and had later taken on malignant degeneration. Again, a uterine fibroid tumor has but few vascular attachments and requires but little blood for its sustenance. Therefore, very rarely, if ever, does it become converted into a malignant growth, which needs a large supply of blood for development. For this reason, we find cancers flourishing in the more vascular tissues, such as the cervix uteri, the breasts, the lips and the stomach.

But before I exclude cancer or sarcomatous tumor, it is right for me to examine her womb. I find that this organ is movable and healthy, and that the tumor has apparently no connection with it. You see that the sound gives a measurement of only three inches, and the motion communicated to the tumor does not agitate the sound. Yet it might possibly be a pedunculated fibroid of the womb, with high parietal attachments. Why then, does it not grow smaller after the menopause? As a broad rule with, however, some exceptions, uterine tumors that grow larger or make their first appearance after the menopause are usually malignant.

I must confess that I am puzzled, so let me go over her history again: She says that this tumor began in the right side, high up and, in fact, it encroaches upon the liver. Now here is a special point that I wish you to remember. If this were a growth from the liver, I should not have this narrow ribbon of resonance between the tumor and liver, hence it is not hepatic. But the growth dips down on the right side toward the kidney and extends horizontally across to the abdomen. Yet her micturition is not frequent. Her urine has been examined with negative results, and she persists in saying that she has had this tumor for six years. (The patient was now removed.)

I confess, gentlemen, that I am perplexed in making a diagnosis. I can not but think that we have here a malignant growth, either a sarcoma of the omentum or a malignant tumor of the right kidney. The pain, the increase in size since the menopause, the septic symptoms, the nodulous character of the tumor, the age of the

woman, all point to malignancy. In view of this doubt in my mind I shall get this woman to stay here in the hospital for some time, both that I may watch her symptoms and otherwise study her condition, and also that she may have the proper food and be built up; for she is now in too weak a condition to undergo an operation. After she has improved I shall make an exploratory incision into the abdomen and be governed by what I shall find.

After all then, gentlemen, instead of teaching you how to make a diagnosis, I have taught you, what perhaps is as important, how not to make a diagnosis. It is very humiliating for a specialist on abdominal tumors to confess that he is puzzled to make a diagnosis in this or any other case: But, gentlemen, you will find out when you get to be as old as I am, how little you actually do know. Often, time will throw light on an obscure case. Then an exploration incision will throw more. But even this will sometimes fail, for last week I removed before you a very large pelvic tumor, the nature of which I do not know. Both ovaries and tubes were healthy and left behind, yet there was a pedunculated tumor coming off from the broad ligament. I sent it to Dr. Formad, but have not yet got a report from him.

#### FIBROID TUMOR WITH ADHESIONS.

This is an interesting case which Dr. Taylor and I treated in conjunction. She has multiple fibroid of the womb, which has universal attachments to the pelvic peritoneum. She was brought into the hospital very ill indeed and with all the symptoms of septicæmia, showing the presence of pus somewhere. But we could not discover where it lay. I aided Dr. Taylor in the operation. After cutting down in the median line of the abdomen, he found a womb gnarled with multiple fibroids and with adhesions to all the pelvic organs and tissues so intimate and so numerous, that no topographical outlines could be made out. There were no ovaries, no tubes and no bladder to be recognized. Enlarging the incision, Dr. Taylor discovered behind the tumor and adherent to its whole surface a pus sac. This was accordingly aspirated and found to be full of stinking pus. It was probably an ovary, but so closely adherent to the tumor that it seemed to be growing from it, and there was no possibility of removing it. After washing out the abdomen and especially the sac, the opening of the latter was stitched to the abdominal incision and a glass drainage tube was inserted. The object of the tube was to keep the sac empty, and to make its walls collapse. Just as we put drainage tubes into any kind of abscess, and compress its walls together by bandages, so we put in a drainage-tube into the pus sac, and compressed its walls together by a large pad of cotton and an abdominal binder. The sac was then washed out once a day with carbolized water.

At the end of a week we changed the glass to a rubber tube, which being elastic is not so dangerous. She has done extremely well and the tube has gradually been pushed out by the closure of the abscess, until it goes in only three inches, and in two more weeks she will be ready to go home. These abdominal pus sacs should, when it is possible, be always removed. Yet when they can not be enucleated, it is wonderful how quickly they sometimes will heal up when drainage is employed. They heal up far more quickly than ovarian cysts which can not from adhesions be removed, and which are then treated by drainage.

#### THE TREATMENT OF FIBROID TUMORS BY ELECTRICITY.

There has been a good deal written and said of late in favor of and against the treatment of fibroid tumors by electricity. The extreme positions assumed by the opposing parties have reminded me of the two knights of ancient fable who, after a sore battle to decide whether the statue before them was of gold or silver, fell grievously wounded each one on that side of the statue which his antagonist had first occupied. They then found to their cost, that each one was right and each one was wrong, for the statue had a golden side and a silver side. Each one held a half-truth, between them they held the whole truth. So when I hear one gentleman advocating nothing but the knife for fibroid tumors, and another as earnest in pushing the claims of electricity, I say to myself, each gentleman holds a half truth, but unitedly they hold the whole truth.

There is no doubt that electricity will sometimes stop the hæmorrhage, and this is in itself a great gain; but whether the tumor will ever become smaller or disappear is yet an open question. The advocates of the knife, with much truth contend, that, granting the hæmorrhage is stopped, the ovaries are themselves greatly diseased in cases of uterine fibroid, and no amount of electricity can cure them. This is a strong argument and it has very frequently been verified by me, when removing the ovaries for fibroid tumors. For instance, only three days ago I removed, at my private hospital, the ovaries of a lady on account of a bleeding and painful fibroid tumor of the womb. Each ovary was found to have undergone fibroid degeneration. Usually, in cases of uterine fibroid, the ovaries are either much diseased or they contain pus-cavities. Sometimes, however, the ovaries are perfectly healthy, no matter how large the tumor may be; but these are exceptional cases. On the other hand, at the change-of-life fibroid tumors generally cease to grow, unless they undergo cystic degeneration. In other words, the woman either ceases to suffer, or she recovers her health after the menopause

has become established. Now, if a woman with a bleeding fibroid can by the means of electricity be tidied over to the menopause, a very great point has been gained. But how are we to know when a uterine tumor is benign and amenable to electrical treatment? I can answer this question better by telling you when they are malignant. When uterine tumors appear in woman after the change of life they are usually malignant. If the uterine tumor appears before the change-of-life and, after the change-of-life, keeps on growing, it is generally malignant, unless it happens to be a fibro-cyst. As a broad rule, with the exception of ovarian cysts, all abdominal tumors that appear after the change-of-life, are usually malignant, unless they are of malarial origin.

The subject of the treatment of bleeding and of growing uterine fibroids by means of electricity is the burning question of the day. I am yet on the fence, although I know that in one case, electricity for the time being checked a very bad case of hæmorrhage; in fact it saved my patient from what Homer calls "The purple death." My advice to you is that, if you can not stop the bleeding by the systemic use of quinine, sulphuric and gallic acids, digitalis, ergot or turpentine; or by the internal applications of vinegar, iodine, nitrate of silver, tannic acid or Monsel's solution, you may send the case to a competent electrician.

I put Monsel's solution last, because it is liable to form a firm and hard clot, which stays behind in the womb and undergoes dangerous decomposition. I have nearly discarded it from my gynecological practice, except in rare cases of capillary oozing on the surface of the abdominal walls of the bowels after ovariectomy, and only in those cases in which Paquelin's cautery is ineffectual or it is inadmissible. But you must not suppose that electricity is altogether a harmless remedy. Repeated cases of death have been reported, and I must honestly confess that I am surprised that more have not occurred, considering the heroic dosage of electricity that is resorted to.

## MEDICAL PROGRESS.

**THE COLD BATH IN TYPHOID FEVER.**—M. JOSIAS reports his experience in the systematic use of the cold bath in the treatment of typhoid fever. During the years 1888 and 1889 he has treated in various hospitals 36 cases by this method, giving the bath at 18° every three hours when the bodily temperature reached or exceeded 39°. One patient died, the mortality therefore being 2.77 per cent. Regarding sex 29 patients were males and 7 females. The cases treated may be divided as follows: Benign, regular and hyperpyretic, 27; grave, with or without complications, 9; relapses, in spite of the cold bath,

4; relapses, treated by the cold bath when the cases had previously been treated by another method.

These 36 patients took 2,227 baths at 18°, an average number of 61 for each patient. The baths were always begun as soon as the diagnosis of typhoid fever was definitely determined, and they were never suspended except temporarily in cases of intestinal hæmorrhage. Menstruation, symptoms of broncho-pneumonia and albuminuria were not regarded as contraindications for the treatment. There was no occasion to regret perseverance in the treatment. Thanks to the baths, the fever exhibited nothing of a typhoid character save the name. Patients treated in this manner are not prostrated; they present no torpor; they remain conscious and lucid; the tongue is moist and thirst is intense, a condition that enables one to administer 4 or 5 litres of alimentary or other fluids daily. There is diarrhœa and excessive polyuria, but these discharges are to be regarded as a means of carrying off the excessive waste of the organism and as consequently of real advantage, the more so because this washing out is effected by the aid of bouillon and milk, whereby the patient secures the advantage of superalimentation the effects of which are easily controlled. The patients above referred to did not lose much in weight and only moderately in strength, losing from 1 to 2 kilo. in eight days, and being able without much effort to get in and out of the bath. The analysis of these 36 cases shows that refrigerating treatment more than any other seems to successfully combat the fever and adynamia and place the patient in the best condition of resistance to the disease. These statistics united to those of MM. Juhel-Renoy and Richard make a total of 130 cases of typhoid fever with 6 deaths, *i. e.*, a mortality of 4.61 per cent.; whereas the general mortality from typhoid fever in the hospitals of Paris is from 14 to 15 per cent.—*La Sem. Méd.*

**ABSENCE OF VAGINA.**—M. PICQUÉ, of Paris, reports the case of a young woman who presented a total absence of the vagina and an infantile uterus. The vulva was normal. There was an absence of all signs of menstruation, although the ovaries were normal; this was probably due to the malformation or absence of the uterine mucous membrane. Following the suggestions of Dolbeau and Le Fort the operator attempted to remedy the principal defect. Amussat's procedure was adopted. A fibrous cord was found which served as a surgical guide but constituted an actual obstruction to the operation itself. The mucous membrane of the vestibule was made to slide back upon the posterior wall of the new vagina, while the integument of the perineum was made to cover the anterior wall. The reporter believes that this manœuvre is useful as a means of pre-

venting subsequent retraction. The results of the operation remain satisfactory five months after the operation.—*Le Bulletin Médical*.

**EARLY OPERATIVE TREATMENT OF PERITYPHLITIS FROM PERFORATION OF THE APPENDIX VERMIFORMIS.**—CHAS. KRAFFT, of Lausanne, seeks to show that the treatment of perityphlitis must be of an operative character. In perityphlitis stercoralis there is perforation of the appendix by a faecal calculus, with the formation of a retro-cæcal abscess containing faecal matter. The abscess should be freely opened, the calculus removed, and the appendix ligated and cut off. The symptoms of perityphlitis are suddenly lancinating and pulsating pains, which are soon localized in the region of the cæcum. The patient, generally a young, powerful man, has bent with diarrhoea and constipation. Palpation early in the case reveals resistance in the right iliac fossa, sometimes dulness. If the diagnosis is certain, one can never operate too soon, though he may often do the contrary. Operation: Typical incision, as for ligation of the right common iliac; after cutting through the abdominal walls either fluctuation is made out, or else one makes an exploratory puncture, in order to locate the abscess; this is freely opened, generally extraperitoneal; the calculus is sought, and the appendix ligated and removed; suture of peritoneum, if the latter has been incised; drainage irrigation daily until the wound has united.—*Volkmann's Kil. Vortr.*

**CURE OF CHOREA BY ELECTRICITY.**—GAUTIER reports a very severe case of generalized chorea in a patient 13½ years old. The patient could not stand erect, nor even sit up straight; neither could he use his hands to dress or feed himself; he could not talk; there was incontinence of urine. From the 16th of July to the 14th of September twenty-six applications of the electrical current were made; duration of each, eight minutes; intensity, first six, then eight, and finally twelve milliampères; direction of current, from the sacrum to the neck. Results: The patient, who at first could not write, became able to do so with neatness and rapidity; the bodily weight increased from 32 to 40 kilo.; he is able to work, and is no longer excitable. The treatment employed before resorting to electricity consisted in the administration of bromide of potassium, sulphur baths, chloral and antipyrin.—*Le Bul. Méd.*

**POSITION OF PATIENT DURING THE LYING-IN PERIOD.**—DR. CULLINGWORTH, in his address on obstetrics before the recent meeting of the Bristol Medical Association, expressed his doubts regarding the wisdom of requiring patients to maintain the horizontal position after parturition. He also took occasion to quote from the writings of Chas. White, who, more than one hundred years ago, advised that lying-in women should be required

to sit upright in bed while nursing their children and while eating, and to kneel while passing water. He gave as his reasons for this advice the prevention of stagnation of the lochia, the avoidance of constipation and retention of urine, and the promotion of uterine contraction.—*Brit. Med. Journal*.

**TOTAL EXTIRPATION OF LARYNX.**—PROF. DEMONS, of Bordeaux, exhibited a patient at the meeting of the French Surgical Congress, upon whom he had performed total extirpation of the larynx, thirty months previously, on account of an epithelioma limited to the right vocal cord. The patient, who is now 58 years old, is in perfect health. He wears no artificial apparatus, and still, thanks to certain movements of the lips and tongue, he is able to speak in a very intelligible manner, though in a very low voice.—*Le Bulletin Médical*.

**A CASE OF POISONING FROM ANTIPYRIN.**—PANSCHINGER reports (*Centbl. für Gyn.*) a case of poisoning by antipyrin in which a new symptom was observed, viz: profuse diarrhoea, which set in a few hours after the last dose was taken. In all 5 grams were taken, 1 gram every hour. Aside from the diarrhoea, the principal symptom was the usual collapse. The patient recovered in ten days. The medicine was obtained from an apothecary, and without a prescription.

**SUBCUTANEOUS INJECTION OF BLOOD BY THE ZIEMSEN METHOD.**—WESTPHALEN reports (*St. Petersburger Med. Wochenschr.*) a case of so-called essential anæmia which occurred suddenly in a man 56 years of age, after an attack of intestinal catarrh with fever. A bothriocephalus latus was discharged and the patient was treated with liq. ferri dialysæ, but no improvement took place in his condition. An examination of the blood showed a notable decrease in the number of red blood corpuscles present (840,000 per cubic millimetre). A subcutaneous injection of 150 ccm. of defibrinated human blood was then administered, and within eight days marked improvement was observed in the patient's condition, which continued until final recovery.

**CHOLELITHIASIS.**—M. ROSENBERG reports (*La Sem. Méd.*) excellent results in cholelithiasis from the administration of large doses of olive oil. Of late he has added menthol to the oil on account of its anæsthetic properties, which serve to lessen the inclination to vomit; cognac is also added to improve the flavor. The reporter has collected the reports of twenty-one cases of this disease, nineteen of which were successfully treated by this method. The explanation of the method of cure is this, that the ingestion of large amounts of oils and fats increases the secretion of bile, and hence favors the expulsion of the calculi.

SATURDAY, DECEMBER 28, 1889.

INTESTINAL SUPERDIGESTION.

An article with this title appears in the *New York Medical Journal* of Nov. 9, from the pen of DR. W. S. CHRISTOPHER, of Cincinnati. The term is used to designate the pathological fermentation of the products of normal intestinal digestion. The author's deductions are based upon well established chemical laws, and, if true, go far toward the explanation of a train of phenomena concerning which our knowledge has been very incomplete.

Christopher's aim is to elucidate the pathology of the intestinal fermentations. He objects to the prevalent idea that fermentation is opposed to digestion; or, in other words, that a food may be either digested or undergo fermentation, but cannot be both digested and fermented. On the contrary he believes that the action of the digestive ferments is usually, if not always, a prerequisite to the action of the microorganisms of pathological fermentation. The process is thus brought into analogy with the alcoholic fermentation of cane-sugar; for it is a well known fact that the latter process cannot occur until the sugar has been inverted; that is, transformed into the two glucoses, dextrose and levulose, by a soluble ferment accompanying the yeast plant and probably produced by it. Superdigestion is always induced by microorganisms, and varies in its results according to the food upon which these develop.

We have therefore superdigestion of proteids,

of fats, and of carbohydrates; and each of these forms is discussed in the paper.

Concerning the superdigestion of proteids, the author tells us that it may also occur in the stomach, but is there less frequent than in the intestine. In the products of tryptic digestion it is exceedingly common. This difference he believes is due less to any doubtful antiseptic action on the part of the gastric juice than to the difference in extent of the digestion or decomposition of the albuminoid molecule produced by the two juices. "The most interesting of the decomposition products of proteids, for our present purpose, are the fatty acids, the ptomaines, and the gases, which latter comprise carbonic acid gas, ammonia, nitrogen, hydrogen, marsh gas, and sulphuretted hydrogen." The ptomaines, the most important of these products are alkaloids, and produce their effect through the agency of the central nervous system. A frequent group of symptoms produced by this putrefaction "comprises constipation, headache, drowsiness, and listlessness, or even marked depression—the so-called biliousness." The author has also seen a group of symptoms comprising "constipation, coma, contracted pupils, slow and shallow respiration, and a depressed heart-action."

But he considers the superdigestion of the carbohydrates the most important as well as the most frequent form of intestinal fermentation in adults. Normal digestion converts all the carbohydrates, starch, cane-sugar, maltose, lactose, into glucoses. Subsequent fermentation may convert the glucose into alcohol with liberation of carbonic acid gas; or into one of several fatty acids, which in turn breaking up give rise to carbonic acid gas, and hydrogen or marsh gas. The clinical features and the treatment of this form of fermentation were presented in the report of two cases in which the trouble had been diagnosed and successfully treated. The most prominent symptoms were constipation, tympanites, and abdominal pain. The chief feature of the treatment was the withholding of those articles of diet (carbohydrates) in the products of whose digestion the abnormal fermentation was believed to have occurred. However, since total abstinence from the carbohydrates for any length of time is next to impossible, (and this implies the exclusion of milk on account of its contained sugar,) the author recommends the allowance of

a small amount of farinaceous food and the administration therewith of an active diastatic ferment by means of which the starch may be digested in the stomach.

We doubt not that Dr. Christopher has given us a true explanation of a certain number of cases of intestinal fermentation; in other words, that he has described a possibility. We regret, however, that he has not given us some data in support of his assertion that this is the most frequent form of intestinal fermentation beyond the fact such is his individual belief. The frequency with which we encounter in these cases gross errors in diet with the passage of undigested food, especially in children, is sufficient evidence that fermentation may occur in food that has wholly or in part escaped the action of the digestive juices. And although the paper is expressly limited to intestinal fermentations it seems that stomachic fermentations should have been discussed so far at least as to point out the means of distinguishing them from processes occurring in the bowels.

We trust that the author will yet more fully elaborate his theory with especial reference to the relative frequency of superdigestion and its differential diagnosis.

#### CONCLUSION OF VOLUME XIII.

For thirty-four years it had been the custom of the American Medical Association to publish, each year, a single volume containing the Proceedings of the Annual Meeting for that year and such papers as were referred for publication.

As time went on and the Association work was more extended these Transactions became more and more voluminous. The work of editorial supervision came to be a serious one, and the necessary delay incident to publication led to an extended discussion of methods, until finally it was determined that instead of issuing the Transactions in single annual volumes, a weekly medical journal should be substituted, in which during each year the entire proceedings of the Association for that year and the papers read in the several Sections should be published, and in order that THE JOURNAL might be still more valuable to the members, it was decided to provide for the publication in its columns of such other original and selected matter as would justly entitle it to a prominent place among the leading medical periodicals of the day.

It was not without solicitude that the Trustees charged with the responsibility of conducting this enterprise assumed the duties thus assigned to them. They were fortunate in securing such editorial and financial ability combined in the person of an Editor-in-chief that from the first THE JOURNAL was able to command for itself the confidence of the profession and to attain a sound financial basis. After five and a half years of untiring labor the Editor desired to be relieved of the responsibilities of his position, and at his earnest solicitation his resignation was accepted. It was then decided to continue the publication of THE JOURNAL under the direction of the Board of Trustees, and that its immediate supervision should be vested in a special Board of Management. Under that supervision the volume closing with the present number has been edited and published.

The same careful oversight as in former years has been exercised with reference to the finances of THE JOURNAL. Its receipts at the office of publication during this as compared with the previous year have been somewhat increased, while the expenses of publication have been diminished. If the payments of annual dues by the members shall be as prompt as in former years, we see no reason why in the future THE JOURNAL may not only continue free from debt, but material additions be made which would enhance its value to members and subscribers.

It is the sincere desire of THE JOURNAL to reflect fully and impartially the interests and the wishes of the Association, and to labor for its upbuilding in every legitimate way. It desires to be in full accord with every honorable effort for the educational improvement of the medical profession of our country, and for the *unification* of all medical interests. It seeks the hearty support of the entire membership of the Association, and will earnestly unite in the effort to extend that membership until the Association shall have a strong and influential representation in every State in the Union. It is grateful for the courtesies so freely accorded by other medical journals, and in seeking to develop its own interests, will be as studiously careful in no wise to imperil theirs.

At the close of another volume, THE JOURNAL craves for each member of the Association only pleasant memories of the old year, and tenders its greetings for the *New*.

## EDITORIAL NOTES.

## HOME.

THE LIBRARY OF THE LATE DR. BAUER, the celebrated German scholar of Leipsic, has just been purchased by the Haverford, Pa., College for a large price. It consists of 8,000 volumes on ecclesiastical literature and history.

THE UNIVERSITY OF CINCINNATI contemplates the establishment of a Medical Department. The aim is to so richly endow it as to make it rival if not eclipse the existing institutions of this region. The project is as yet chimerical, however, the source from which the phenomenal endowment shall come not having been ascertained. There is at present a nominal connection between the University and nearly all the other educational institutions of the city, by which the two leading medical colleges, the Ohio, and the Miami are designated as the Medical Department of the University of Cincinnati, and this is about as close as the relation is likely to become, notwithstanding the fact that a correspondent of an eastern medical journal, probably in a facetious moment, hints at the possible collapse of the now prosperous medical colleges, should the University prove successful in its project. Certainly the old institutions, particularly the Medical College of Ohio, established in 1819, will not voluntarily close their eventful histories and begin anew in 1890.

DEATH UNDER ETHER.—At Bellevue Hospital a death under ether, used as an anæsthetic, recently took place, during an operation for abscess in the neck. At the autopsy, the kidneys were found to be diseased, through cystic degeneration.

DR. J. J. KANE, for a number of years a surgeon in the United States Army, has recently been appointed one of the attending surgeons to St. Mary's Hospital, Cincinnati.

MEDICAL DIRECTOR J. S. BILLINGS.—Dr. John S. Billings has been invited to take the position of Medical Director of the University Hospital at Philadelphia. The Secretary of War, and the Surgeon-General of the Army, have signified their approval and Dr. Billings will assume this new function, without change of official duties in the Surgeon-General's office.

THE LIFE-SAVING SERVICE.—The annual report of the Life-Saving Service of the United

States Government, for the last fiscal year, shows that the number of persons involved in the operations of the department was over three thousand, the number of persons saved or succored, 787, number of those lost, 42. The cost of maintenance last year was \$293,000.

A NEW CHARITABLE INSTITUTION, known as Christ's Hospital, has recently been established in the West End, Cincinnati. It is conducted by a corps of qualified physicians under the auspices of the Methodist Episcopal Church.

## FOREIGN.

A FEVER-HOSPITAL DESTROYED BY FIRE.—At Rochester, England, the Fever-Hospital was destroyed by fire, November 29. There were fifteen patients there at the time, and all were rescued by the nurses, although with no little difficulty and risk.

DISINFECTION OF BARBERS' INSTRUMENTS.—Several cases of transmission of contagious diseases by barbers' instruments having come to light at Nordhausen, the police of that city has passed an ordinance enjoining all barbers, under penalty of the law, to disinfect their instruments by immersion in a solution of carbolic acid or creolin after being used.

CRUSADE AGAINST ALCOHOLISM.—The Government of Belgium has decided to combat, as far as possible, the progress of alcoholism. After demanding and obtaining from Parliament a law permitting the exaction of a license fee for new public houses of a greater or less amount, according to the population of the locality, it has also raised the subsidy which it grants to the Patriotic League Against Alcoholism from 500 to 1,000 francs.

MEDICAL STUDENTS IN THE EUROPEAN UNIVERSITIES.—A recently published University calendar shows the following attendance of medical students during the summer semester of 1889: Vienna, 2,064; Munich, 1,462; Berlin, 1,186; Würzburg, 983; Dorpat, 931; Leipzig, 874; Graz, 586; Krakau, 522; Freiburg, 452; Greifswald, 422; Bonn, 402; Breslau, 380; Halle, 337; Kiel, 316; Erlangen, 301; Strassburg, 300; Heidelberg, 297; Zürich, 288; Innsbruck, 285; Königsberg, 266; Tübingen, 265; Bern, 251; Marburg, 236; Göttingen, 227; Jena, 226; Giessen, 173; Rostock, 155; Basel, 109.

## TOPICS OF THE WEEK.

## BANTOCK'S VIEWS OF LISTERISM.

As an appendix to a paper on "Hyperpyrexia after Listerian Ovariectomy," read before the Royal Medical and Chirurgical Society in December, 1880, DR. BANTOCK published a table of 162 cases of completed ovariectomy. In the November number of the *British Gynecological Journal* of this year he publishes a table including remarks on 238 additional cases, bringing his total list to 400. It is extremely interesting to survey the results and the methods of this eminent surgeon, who says that in 1881 there were only two men, as far as he knows, who ventured to perform ovariectomy without a rigid observance of all the details of the Listerian method. These two men were Mr. Lawson Tait and himself. In speaking of the present state of the Listerian method he says in England, at least, it is a very rare thing to see the spray in use at all. In the Samaritan Free Hospital it has been discarded by all of his colleagues with but one exception. And he adds it is making no assumption when he says that this is due to the superior results which he has obtained there since he resorted to a more rational and more simple method. Still, he adds, the belief in so-called antiseptics has a firm hold on many minds, and although the belief in the efficacy of the spray has wellnigh died out, it is not so with other details of the method. For whether it be carbolic acid, or corrosive sublimate, or boracic acid, or whatever it may be, few operators venture to perform an operation without employing one of these agents for the hands, sponges and instruments.

As a proof that he is making no assumption when he says that his results led to the discarding of the spray in the Samaritan Hospital he gives the following results: He confines himself to the cases of ovariectomy, and records it as a fact that from April, 1885, to October, 1888, a period of three years and a half, he did not lose a case in that hospital with a series of ninety cases. While on the other hand, during this period the mortality under the Listerian method exceeded 12 per cent. Moreover, he affirms that his patients recovered with less pyrexia than under the carbolic acid treatment. As an excuse for recurring to this question once more—he hopes for the last time—he gives the fact that he is constantly learning that there still exists a belief that he employs some form of so-called antiseptic in his operations. Once for all, then, he wishes to repudiate, and in strong and unmistakable language he does so.

For his hands, instruments and sponges, he uses plain water; he takes no precaution to sterilize it, "as it is called," by boiling; he regards water that is fit for drinking and household purposes generally as suitable for the purpose of any operation; that while the water is heated—but not necessarily boiled—he has no hesitation in cooling it down, if too hot for his hands, with cold water drawn fresh from the tap; as, for instance, when washing out the peritoneum, and that he pays the greatest attention to cleanliness and sees that all utensils are as clean as water can make them. He washes his hands very

carefully before commencing an operation, making them as clean as soap and water and a nail-brush can make them, and he frequently cleanses them during the operation. He goes so far as to use the nail blade of his pocket knife for removing all matter from under his nails after washing, without adopting "that refinement of absurdity" which consists in previously passing the blade through the flame of a spirit lamp. As a covering to the wound he employs simple absorbent gauze, perfectly innocent of any germicide or foreign substance. And such is his belief in the hurtfulness of "germs" that, were it not for other considerations, he would leave all his wounds exposed to the air—as, for example, he has sometimes done in amputation of the breast, and always in the operation for restoring a ruptured perineum.

What, then, he says, are the results of this method, speaking generally? They are these, viz.: that while in his first hundred ovariectomies, the majority having been done under the Listerian method or a modification of it, he lost nineteen cases, in his second hundred, while he was gradually abandoning this method, the mortality fell to fourteen; in the third hundred, all performed with plain water, the mortality was eight, and in the fourth hundred it was only four.

In the general management of an ovariectomy, in several particulars his practice differs materially from that of nine years ago.

1. *Washing out the Peritoneum.*—The writer gives a very interesting history of how he gradually adopted this method, without precedent to work by, until he reached his present state of perfection. At first he used whatever came most conveniently to hand—a pint or a quart jug, or a clean Higginson's syringe—but for a considerable period he has used Lawson Tait's apparatus, which he has improved by adding a ball free from valves to facilitate the starting of the siphon action. A full stream of water, such as this apparatus gives, removes all clotted and fluid blood, serum, débris of broken-up ovarian tumor, or fibrinogen, much more effectually than it is possible to do by any other means, and without any irritation of the peritoneum. It is especially useful in cases of ruptured colloid tumor, for the warm water rapidly dissolves out the colloid matter, which in these cases is so frequently found attached to the omentum, appendices epiploicæ, etc. He has never known evil results follow the use of water, but he has several times regretted that he did not resort to it. Nor is he at all particular in getting all the water away. In ruptured colloid tumor, every one who has had experience, he says, knows that the peritoneum is usually covered with a very delicate layer of capillaries, the slightest sponging of which causes serious injury and oozing. In these cases also I remove no more water than comes to the surface. In a long discussion of the bad results obtained by other operators in washing out the peritoneum, Dr. Bantock attributes these results to the employment of some form of antiseptic materials in the water which become absorbed or in some way poison the patient. He says it is too late to deny the possibility of the absorption of carbolic acid by the peritoneum. There are too many observations on record to prove the fact beyond a doubt. We know also that as

in the case of corrosive sublimate or any mercurial preparation, some persons are peculiarly sensitive to its action, and that while in a large majority of cases no harm may accrue, yet now and then a case is met with in which this idiosyncrasy exists. This is the only rational way of accounting for the large number of deaths due to the use of carbolic acid, and more especially corrosive sublimate. He protests, then, against the employment of any so-called germicide substance in flushing the peritoneum, and cannot too strongly insist on confining the surgeon to plain water as at once perfectly innocuous and thoroughly efficient.

2. *The Treatment of the Pedicle.*—In the beginning of the year 1876, dissatisfied with the clamp, he announced his intention of exclusively employing the ligature until he had settled the question to his own satisfaction. Since the 25th of November, 1875, he has used it exclusively, and he has now the satisfaction of witnessing its almost universal adoption. He soon, however, found that there were difficulties in the way, for he lost his nineteenth case from the slipping of the outer edge of the pedicle—that edge which consists of two folds of the peritoneum with its contained vessels. To obviate this source of danger he adopted the plan of first securing this fold by a separate ligature before transfixing for the main ligature. He prefers the figure of eight loop in the ordinary cases.

3. *Opium.*—It was about the time he resorted to flushing the peritoneum that he also discontinued the use of opium after operations. His mortality, he calls attention to, has been under 4 per cent. since discontinuing its employment. Not only have the patients recovered in larger numbers, but they have recovered better.

4. *General After-treatment.*—(a) *Vomiting.* It is now a long time since he came to the conclusion that the best way of arresting sickness was to keep the stomach as quiet as possible by preventing anything getting into it. No food is allowed for many hours after operating. He prefers operating in the morning for that reason. If the stomach is found to contain some watery mucus which the patient is unable to get rid of by vomiting, a few ozs. of hot water will usually suffice to clear out the stomach. (b) *Thirst.* For this distressing desire the patients are allowed to rinse their mouth with warm water. Ice in any way is not tolerated. (c) *Peritonitis.* According to this writer peritonitis arises from causes operating within the peritoneal cavity and causes outside of it. The chief of the former, which he does not stop to enumerate, can be obviated largely by the use of the drainage tube. Or the scraping of the peritoneum may be found necessary. The latter can be relieved oftentimes by removing the offending material from the intestinal canal. This he prefers to do by means of injections. In the condition in which Tait and Smith give salines he believes in adopting the opposite course. In his experience purgatives have always aggravated the condition.

#### DR. H. NEWELL MARTIN'S LECTURES.

Dr. H. Newell Martin is delivering a series of lectures upon the "Relations of Psychology to Physiology," at Johns Hopkins College.

## PRACTICAL NOTES.

### DANGER OF LAPAROTOMY PERFORMED BY GAS LIGHT.

ZWEIFEL has observed on several occasions when laparotomy has been performed by gas light, that not only the patient, but the operators experienced a slight roughness of the throat, especially when the operation was a protracted one. Several patients who had undergone operations at the Gynecological Clinic at Leipsic, in which this roughness was experienced, subsequently developed catarrhal pneumonia. A patient who had completely recovered after operation afterwards succumbed to this pulmonary inflammation. The cause is sufficiently obvious. The chloroform becomes decomposed by the light of gas or petroleum. The smell of the products of this decomposition has sometimes become so pronounced that it has been thought some material was burning in an adjoining chamber.—*Gazette de Gynécologie.*

### A NEW DUSTING POWDER.

DR. KIEZER publishes an interesting paper on the use of salol as a dusting powder. He applied it in the following combination:

Salol . . . . .	5j.
Amylum powder . . . . .	5j.

A varicose ulcer, in which all kinds of treatment had invariably been tried, was nearly completely cicatrized six weeks after the first application of salol. Six other cases of ulcerated leg were treated with the salol dusting powder; in all of them except one the success was equally marked as in the first case. Excellent services were also rendered by the dusting powder in cases of sycosis, burns, scalds, wounds, defects of the skin, etc.—*Prov. Med. Journal.*

### ON THE PROPHYLACTIC VALUE OF PULMONARY GYMNASTICS.

DR. GÆTHIGENS, of Riga, points ("Proceedings of the Riga German Medical Society," 1889, p. 547) to a great prophylactic value of systematically training the lungs. A thorough ventilation of the organs, more especially of their apices, requires a certain muscular strength, as well as an erect carriage of the body. Even in persons with a normally-built chest an habitual defective respiratory action is followed, in course of time, by a permanent pulmonary weakness and a decrease in the capacity of resistance towards any pathogenic principles finding their way into the lung. In subjects with an hereditary phthisic predisposition—that is, in subjects with a poorly-made chest, flabby muscles and lowered power of resistance—the dangers of a defective respiration are

still by far greater. In addition, in either of the categories the dangers are not limited to a train of pulmonary diseases, but also include various anæmic or chlorotic disturbances, as well as nervous affections. Hence, the pulmonary gymnastics are of a paramount practical importance, and should be systematically resorted to in all children, and that at a possibly early age. In other words, every child's respiratory organs should be methodically trained by means of certain physical exercises, consisting mainly of steady and deep respirations in free air, the child standing or walking in a perfectly upright position. Once the habit of thoroughly ventilating the lungs has been firmly established by a training course of this kind, the child unconsciously or instinctively retains it for life. The author is about to initiate the gymnastic courses of this sort on a large scale.

## ASSOCIATION NEWS.

### American Medical Association—Forty-first Annual Meeting.

#### *Section of Obstetrics and Diseases of Women.*

The officers of the Section of Obstetrics and Diseases of Women respectfully request those who desire to read papers in that Section at the meeting of the American Medical Association to be held in Nashville, Tenn., May 20-23, to communicate the titles thereof to either of the undersigned not later than January 15, 1890.

WILLIAM WARREN POTTER, Chairman,  
284 Franklin St., Buffalo, N. Y.

JOSEPH HOFFMAN, Secretary,  
126 W. Diamond St., Philadelphia, Pa.

## MISCELLANY.

**JABORANDI AND THE HAIR.**—Some discussion has taken place as to the use of jaborandi in connection with the hair. The senior surgeon to the London Skin Hospital states that it is a valuable drug in the treatment of diseases of the hair, promotes the growth in certain cases and influences the color in others. He deprecates its use, however, except under medical advice.—*British and Colonial Druggist*.

### *Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from December 14, 1889, to December 20, 1889.*

By direction of the Secretary of War, Lieut.-Col. Charles T. Alexander, Surgeon, will be relieved from duty as Medical Director, Dept. of the Columbia, on receipt of this order at the Hdqrs. of that Dept., and will report in person to the Commanding General, Div. of the Atlantic, for the purpose of preparing for, and becoming familiar with, the duties of attending surgeon in New York City. He will also, upon his arrival in New York, assume the duties of examiner of recruits in that city. Major William F. Waters, Surgeon, will take temporary charge of the office of Medical Director, Dept. of the Columbia, upon the relief of Lieut.-Col. Alexander, and perform the duties pertaining thereto. S. O. 291, A. G. O., Washington, December 14, 1889. First Lieut. R. R. Ball, Asst. Surgeon, is relieved from temporary duty at Ft. Sill, I. T., and will return to his proper station, Ft. Riley, Kan. S. O. 182, Hdqrs. Dept. of the Missouri, Ft. Leavenworth, Kan., December 12, 1889.

With the approval of the Secretary of War, the leave of absence granted Capt. C. N. B. Macaulay, Asst. Surgeon, in S. O. 166, Dept. Mo., November 8, is extended one month. Par. 10, S. O. 294, A. G. O., December 18, 1889.

Capt. George McCreery, Asst. Surgeon U. S. A. (Ft. Warren, Mass.), is granted leave of absence for one month, to take effect upon the arrival at that post for temporary duty of Capt. Samuel Q. Robinson, Asst. Surgeon. Par. 6, S. O. 289, Div. Atlantic, December 18, 1889.

Capt. Samuel Q. Robinson, Asst. Surgeon U. S. A. (Ft. Hamilton, N. Y. H.), will proceed without delay to Ft. Warren, Mass., and report to the post commander for temporary duty. Par. 5, S. O. 289, Div. Atlantic, December 18, 1889.

### *Official List of Changes in the Medical Corps of the U. S. Navy for the Week Ending December 21, 1889.*

Asst. Surgeon I. W. Kite, promoted to be a P. A. Surgeon, U. S. N.

Asst. Surgeon E. P. Stoner, promoted to be a P. A. Surgeon, U. S. N.

Asst. Surgeon O. D. Norton, promoted to be a P. A. Surgeon, U. S. N.

Asst. Surgeon Chas. P. Henry, placed on the Retired List, U. S. N.

Asst. Surgeon Geo. McC. Pickerell, ordered to Navy Yard, Washington, D. C., for temporary duty.
